In this chapter we will assess the current ecological understanding of the rhizosphere in agroecosystems and broaden the scope of rhizosphere contributions to encompass a variety of ecosystem functions beyond those directly related to maximizing crop growth and yields. Our aim is to examine the potential for rhizosphere processes and plant-microbial interactions to restore agroecosystem functions to reduce input dependancy and environmental degradation. We begin with an inventory of how conventional, high input management has altered the soil environment and biota in agroecosystems with particular emphasis on the consequences for the rhizosphere habitat. We then survey a range of rhizosphere processes and examine how current management practices enhance or hinder the process and evaluate the potential for improved functionality. Finally, we look ahead and discuss how management of the rhizosphere and plant-microbial interactions could be approached within multifunctional, ecologically-sound agricultural systems of the future.

title: Designed to 'Effectively Frustrate': Copyright, Technology, and the Agency of Users
abstract: Recently, the major U.S. music and movie companies have pursued a dramatic renovation in their approach to copyright enforcement. This shift, from the ?code? of law to the ?code? of software, looks to technologies themselves to regulate or make unavailable those uses of content traditionally handled through law. Critics worry about the ?compliance? rules built into such systems: design mandates for manufacturers indicating what users can and cannot do under particular conditions. But these are accompanied by a second set of limitations: ?robustness? rules. Robustness rules obligate manufacturers to build devices such that they prevent tinkering -- not only must the technology regulate its users, it must be inscrutable to them. I

examine this aspect of technical copyright regulation, looking particularly at the CSS encryption system for DVDs and the recent ?broadcast flag? proposed for digital television. In the name of preventing piracy, these arrangements threaten to undermine users? sense of agency with their own technologies.This research was assisted by a grant from the Digital Cultural Institutions Project of the Social Science Research Council, with funds provided by the Rockefeller Foundation.

title: Engineering a Principle: 'End-to-End' in the Design of the Internet
abstract: The term 'end-to-end' has become a familiar characterization of the architecture of the Internet, not only in engineering discourse, but in contexts as varied as political manifestos, commercial promotions, and legal arguments. Its ubiquity and opacity cloaks the complexity of the technology it describes, and stands in for a richer controversy about the details of network design.
This essay considers the appearance, in the 1970s, of the term 'end-to-end' in computer science discourse, and how the term became a point of contention within disputes about how to build a packet-switched network. I argue that the resolution of some of those disputes depended on the transformation of the term from descriptor to 'principle'. This transformation attempted to close specific design debates, and, in the process, made the term dramatically more useful in those discourses beyond engineering that eventually took a keen interest in the design of digital communication networks.
The term, drawn from common parlance and given not only meaning but conviction, was shaped and polished so as to be mobile. As such, it actively managed and aligned disparate structural agendas, and has had subtle consequences for how the Internet has been understood, sold, legislated, and even re-designed.

title: Copyright and Commerce: The DMCA, Trusted Systems, and the Stabilization of Distribution
abstract: The Digital Millennium Copyright Act has been criticized for granting too much power to copyright holders, offering them new technological controls that may harm the public interest. But, by considering this exclusively as a copyright issue, we overlook how the DMCA anticipates a technological and commercial infrastructure for regulating not only copying, but every facet of the purchase and use of cultural goods. In upholding the law in Universal v. Reimerdes, the courts not only stabilized these market-friendly arrangements in cultural distribution; they extended these arrangements into realms as diverse as encryption research and journalism, with consequences for the very production of knowledge.

title: Using alteration halos to determine the mass of volatiles expelled and the rate of expulsion in a magmatic porphyry system with application to the porphyry copper system at Butte, Montana
abstract: The rate of volatile expulsion, the duration of venting, the total volume of volatiles expelled, and the size of intrusion required to supply them are key parameters in the formation of any magmatic-hydrothermal ore deposit that can be estimated from the morphology of the hydrothermally altered rock. The radius of pervasively altered rock around the fluid source and the taper of alteration halo with distance from the

pervasively altered zone constrain the duration and rate of volatile expulsion. The volume of altered rock records the total mass of volatiles expelled. An analysis of the Pittsmont Dome at the porphyry copper system at Butte, Montana provides an example. The moles of hydrogen ion consumed during alteration are calculated from the mineralogy of unaltered and altered rock. Published composition estimates are used to determine the concentration of reactable hydrogen ion in the magmatic fluid. Diffusion from the vein to a reaction front at the edge of the halo surrounding it constrains the rate of hydrogen ion loss from the vein. Semi-analytic and finite difference simulations of alteration halo formation show how the radius of the pervasively altered zone and the steepness of the taper beyond that zone depend on the rate of volatile expulsion; the faster the fluid velocity, the less steep the taper. Data from the Pittsmont Dome suggest 23 to 30 billion tons of magmatic fluid was expelled over a period of less than 20 years. Assuming 5 wt% magmatic water in the porphyry intrusion, a spherical intrusion ~7 km in diameter is needed to supply the volatiles for just this part of the Butte mineralization system.

title: MODERNIZATION AND URBAN MONASTIC SPACE IN RATTANAKOSIN CITY: COMPARATIVE STUDY OF THREE ROYAL WATS
abstract: MODERNIZATION AND URBAN MONASTIC SPACE IN RATTANAKOSIN CITY: COMPARATIVE STUDY OF THREE ROYAL WATS
Worrasit Tantinipankul, Ph.D. Cornell University 2007 This dissertation is about the changing physical conditions and social meanings of royal Buddhist monastic complexes (wat) in the Rattanakosin Historic District from the beginning of the Bangkok period to the 1997 economic crisis. In the pre-modern period, the royal wat was the key site for the ruler to consolidate his power and establish his legitimacy as a righteous Buddhist monarch. In this traditional context, these Buddhist monastic complexes became the centers for accumulating and redistributing wealth surplus in various forms of public facilities. With the advent of the modern era, the royal monastic complexes acquired new meanings and functions associated with the process of nation-building, becoming at once symbols of national heritage, loci for modern education, and models of development. And yet, paradoxically, because of the Thai state?s adoption of the Western philosophy of the separation of church and state, the royal monastic complexes which previously functioned as public facilities became more private and centralized under the power of the ecclesiastical authority. Moreover, the monastic land ownership and their space have largely been neglected in Bangkok's urban planning. Monastic communities are not only invisible in the plans for Bangkok's urban development, but they are also responsible for generating their own revenue and for the management of their monastic properties.
Comparing three case studies of royal monastic complexes, I show how changes associated with the making

of the modern nation-state, including government policies in the affairs of Buddhist religion, transformations in the political economy, and the urbanization of Bangkok, have affected the form and meaning of Buddhist wats. A central aim of this comparative approach is to demonstrate that these changes have not had uniform effects. Rather, as my case studies show, each of these three royal monastic complexes has responded differently to modernization and nation-building depending on the location and size of the monastic donated land, the scale of its major structures, the degree of architectural elaboration, and its social network. In conclusion, the study of problems and historical changes in each royal wat serves to pinpoint what is overlooked in current planning and preservation practice.

title: Ready Insights for the Future: Digital Dissemination of Agronomic and Environmental Knowledge Involved in the Agricultural Development of Central Brazil
abstract: Long-term agricultural development of a major region usually involves supportive national policy, infrastructure development, financial investment and favorable market factors. The remarkable growth of food production in the Savannah region of central Brazil, however, also reflects significant contributions from new technology developed in the area. Some of the early research under-girding the development of this region, locally known as the "cerrado," was conducted at a Brazilian research facility, now known as the CPAC (Agricultural Research Center for the Cerrado). Collaborative work was done there by local researchers and several US institutions, with the sustained and effective support of US government programs aimed at improving long-term world food production.
Information about this unusual success story can be found scattered among the libraries of various institutions and agencies in differing languages and countries. Original objectives, methodology, findings and some of the anecdotal experiences of individuals involved may reside in research theses as well as in scientific journals and extension bulletins. Because this story began some four decades ago, some of it is found as personal remembrances and collected wisdom within the minds, and perhaps in the file cabinets, of now-retired persons.

Current digital technological developments appear to offer unprecedented opportunities to organize and store such information in readily and widely accessible forms. Described as "subject-based digital repositories," these offer a means of collecting material and offering it world wide in a cost-efficient manner. Searchers with diverse interests ranging, as examples, from soil, agronomic and environmental sciences to international economics, policy or history would all have access to knowledge that could contribute to new insights about designs for long-term experiments or strategies for resource development. Research findings and raw data from this specific agricultural ecosystem may apply to similar regions under differing political jurisdictions to meet new challenges as the future unfolds. Such areas and topics could be well served by this repository of knowledge.

We describe such a repository, currently being developed by Mann Agricultural Library at Cornell University in Ithaca, New York. It would focus on programs conducted by the Brazil Cerrados Agricultural Research Center/Cornell University/North Carolina State University cooperative research project during the 1970?s and 1980?s. This was a multi-university collaboration with EMBRAPA, a Brazilian public enterprise. This mutually beneficial project involved several institutions and dozens of researchers, and it contributed significantly to development of the productivity and influence of today's agriculture in the Brazilian Cerrados.

Materials offered in this ?Brazil Cerrados digital repository? would include non-copyrighted text, citations to published documents, personal reflections about key methods and experiences, context photography with explanatory captions and specially-authored analyses or interpretations. Depending upon interests, even interactive virtual discussions could occur.

This digital material will exist as a collection within Cornell University's Open Access Archive (http://dspace.library.cornell.edu/), which is powered by DSpace. A DSpace "community" will be created for Cerrados with "collections" added for organizing the material. Basic indexing (or metadata) will be created for each item deposited. The material may then be accessed via a direct URL or by searching within DSpace or the Cerrados "community" by author, title, or keyword. Browsing by author, title, and date is also allowed. The materials added to DSpace are also searchable via popular search engines such as Google, which will permit the information to be easily located and used by people around the world.

title: A STUDY OF EXCLUSIVE SEMILEPTONIC D DECAYS TO PSEUDOSCALAR PION AND KAON FINAL STATES WITH THE CLEO-C DETECTOR.
abstract: Using a sample of 1.85 million $D\bar{D}$ mesons collected at the $\Psi(3770)$ with the CLEO-c detector, and a reconstruction method based on the full event hermeticity, we measure branching fractions and branching fraction ratios for the four exclusive semileptonic decay modes $D^0 \to \pi^- e^+ \nu$, $D^0 \to K^- e^+ \nu$, $D^{+} \to \pi^0 e^+ \nu$ and, $D^{+} \to \bar{K}^0 e^+ \nu$. For the branching fractions we find ${\cal B}(D^0 \to \pi^- e^+ \nu) = 0.299 \pm 0.011 \pm 0.008 \;\%$, ${\cal B}(D^0 \to K^- e^+ \nu) = 3.55 \pm 0.03 \pm 0.08 \;\%$, ${\cal B}(D^+ \to \pi^0 e^+ \nu) = 0.371 \pm 0.022 \pm 0.013 \;\%$ and ${\cal B}(D^+ \to \bar{K}^0 e^+ \nu) = 8.53 \pm 0.13 \pm 0.22 \;\%$. The ratios are found to be ${\cal B}(D^0 \to \pi^- e^+ \nu) \slash {\cal B}(D^0 \to K^- e^+ \nu) = 0.084 \pm 0.003 \pm 0.001$, ${\cal B}(D^+ \to \pi^0 e^+ \nu) \slash {\cal B}(D^+ \to \bar{K}^0 e^+ \nu) = 0.044 \pm 0.003 \pm 0.001$, $\Gamma(D^0 \to \pi^- e^+ \nu) \slash \Gamma(D^+ \to \pi^0 e^+ \nu) = 2.04 \pm 0.14 \pm 0.08$ and $\Gamma(D^0 \to K^- e^+ \nu) \slash \Gamma(D^+ \to \bar{K}^0 e^+ \nu) = 1.06 \pm 0.02 \pm 0.03$. In addition, form factors are studied through fits to the partial branching fractions obtained in five q^2 ranges. Combining our results with recent unquenched lattice calculations we extract the CKM matrix elements $|V_{cs}|$ and $|V_{cd}|$. Averaging over isospin conjugate modes, we find $|V_{cs}| = 1.01 \pm 0.01 \pm 0.01 \pm 0.11$ and $|V_{cd}| = 0.217 \pm 0.010 \pm 0.004 \pm 0.023$.National Science Foundation U.S. Department of Energy Natural

title: Mechanisms of Zinc Tolerance in the Heavy Metal Hyperaccumulator Thlaspi caerulescens
abstract: The main objective of this dissertation was to identify and examine the mechanisms conferring zinc tolerance used by the zinc and cadmium (Zn/Cd) hyperaccumulator, Thlaspi caerulescens, a plant that has been extensively studied for its altered physiology leading to increased metal tolerance and shoot metal accumulation. Three projects were carried out to address the question of extreme metal tolerance that is one of the hallmarks of this species.
The first project, isolation and characterization of a putative vacuolar zinc transporter, MTP1, found higher expression of this gene in T. caerulescens compared with the related non-accumulator, T. arvense. Additionally MTP1 expression increased in response to increasing plant Zn status. When MTP1 was expressed in yeast, Zn accumulation increased; however, no strong phenotype was seen in transgenic Arabidopsis thaliana overexpressing the A. thaliana homolog of MTP1.
In the second project, a T. caerulescens cDNA library was screened for genes conferring Zn tolerance to yeast when grown on high zinc media. A number of genes with widely divergent potential functions were identified including signaling, metabolic and protein regulation genes. These genes, when expressed in yeast, conferred either increased or reduced Zn accumulation, and several were chosen for whole plant studies. One specific gene of interest was PKS4, a serine-threonine kinase, which was associated with increased zinc accumulation relative to wild type yeast strains. Since other members in this kinase family have already been implicated in plant abiotic stress responses, we examined the effect of altered PKS4 expression in planta on heavy metal tolerance.
Finally, T. caerulescens suspension cell lines were created and characterized for the same metal hyperaccumulation traits exhibited in the whole plant (Zn/Cd tolerance, transport and accumulation). From this work, the increased metal tolerance and altered regulation of metal tolerance genes seen in plants was observed, indicating these are traits expressed at the cellular level. We are now able to stably transform these cell lines, which opens up future work testing candidate hyperaccumulation genes using these suspension cells lines.

title: Consumer Cognition and Pricing in the Nines of Oligopolistic Markets
abstract: The paper fully characterizes the Bertrand equilibria of oligopolistic markets where consumers may ignore the last (i.e., the right-most) digits of prices. Consumers, in this model, do not do this reflexively or out of irrationality, but only when they expect the time cost of acquiring full cognizance of the exact price

to exceed the expected loss caused by the slightly erroneous amounts that are likely to be purchased or the slightly higher price that may be paid by virtue of ignoring the information concerning the last digits of prices. It is shown that in this setting there will always exist firms that set prices that end in nine though there may also be some (nonstrict) equilibria where a non-nine price ending occurs. It is shown that all firms earn positive profits even in Bertrand equilibria. The model helps us understand in what kinds of markets we are most likely to encounter pricing in the nines.

title: International credit and welfare: A paradoxical theorem and its policy implications
abstract: This paper considers a developing nation that faces a foreign exchange shortage and hence its demand for foreign goods is limited both by its income and its foreign exchange balance. Availability of international credit relaxes the second constraint. We develop a simple model of strategic interaction between lending institutions and firms, and show that the availability of international credit at concessionary rates can leave the borrowing nation worse off than if it had to borrow money at higher market rates. This ?paradox of benevolence? is then used to motivate a discussion of policies pertaining to international lending and the Southern government?s method of rationing out foreign exchange to the importers.

title: Portable Checkpointing for Parallel Applications
abstract: High Performance Computing (HPC) systems represent the peak of modern computational capability. As ever-increasing demands for computational power have fuelled the demand for ever-larger

computing systems, modern HPC systems have grown to incorporate hundreds, thousands or as many as 130,000 processors. At these scales, the huge number of individual components in a single system makes the probability that a single component will fail quite high, with today's large HPC systems featuring mean times between failures on the order of hours or a few days. As many modern computational tasks require days or months to complete, fault tolerance becomes critical to HPC system design.

The past three decades have seen significant amounts of research on parallel system fault tolerance. However, as most of it has been either theoretical or has focused on low-level solutions that are embedded into a particular operating system or type of hardware, this work has had little impact on real HPC systems. This thesis attempts to address this lack of impact by describing a high-level approach for implementing checkpoint/restart functionality that decouples the fault tolerance solution from the details of the operating system, system libraries and the hardware and instead connects it to the APIs implemented by the above components. The resulting solution enables applications that use these APIs to become self-checkpointing and self-restarting regardless of the the software/hardware platform that may implement the APIs.

The particular focus of this thesis is on the problem of checkpoint/restart of parallel applications. It presents two theoretical checkpointing protocols, one for the message passing communication model and one for the shared memory model. The former is the first protocol to be compatible with application-level checkpointing of individual processes, while the latter is the first protocol that is compatible with arbitrary shared memory models, APIs, implementations and consistency protocols. These checkpointing protocols are used to implement checkpointing systems for applications that use the MPI and OpenMP parallel APIs, respectively, and are first in providing checkpoint/restart to arbitrary implementations of these popular APIs. Both checkpointing systems are extensively evaluated on multiple software/hardware platforms and are shown to feature low overheads.

title: Clothing Connections
abstract: Clothing Connections is a classic curriculum, specially designed and written for leaders and volunteers to assist and guide them in sharing a variety of clothing experiences with boys and girls 9 years of age and older. The booklet has been organized into eight different units, all of which provide creative ways for teaching about fabrics, clothing selection and care, dressing for cold and warm environments, sewing skills (without the use of sewing machines!), and recycling techniques. Each unit includes step-by-step directions and background information to help leaders prepare for and conduct the programs, regardless of whether their sewing experience is limited or considerable. Master copies of activity sheets may be duplicated to share with program participants. These handouts highlight the basic concept of each unit, and include directions and patterns for making different items, games, and puzzles. This curriculum is the outgrowth of a program developed by the New York City 4-H home economists for use in youth agency settings such as summer day camps, classrooms, community centers, and after-school programs. Many leaders and young people who have participated in this program have played a major role in determining and revising core projects. Projects can be modified for use with children younger than 9 years of age.

title: Analysis and evaluation of loyalty programs measured on a set of variables for a leading credit card company

abstract: This project was divided into three parts. By storing a large data set in the database system, the data can be efficiently queried to analyze the customer base with reference to size and density, distribution, and vital statistics. First, the current customer portfolio was profiled in terms of demographics, net present value, and transactional behavior. Then the data mining techniques were applied to build empirical models. Here the main technique is the k-means, an algorithm of cluster analysis. Our goal was to find the group that made the most use of the reward programs and the group that was the most profitable for the company. After comparing the characteristics of these two groups, it was found that they were somewhat poorly matched. That means that the current reward program might have some problems, because the more profitable customers were not rewarded more. Second, the lagged regression analysis was used to explore the cause-effect relationship between spending and redemption. This information helped to some extent to judge ?the price of loyalty?. The results showed that there was some correlation between them, and it also provided estimated parameters in the regression models. Last, the current rewards scheme was evaluated and several possible schemes were also come up with. By making some reasonable assumptions and running the cost-benefit analysis, a modified scheme was recommended and it was showed to contribute better revenue for the company and to benefit customers as well.Grupo Uno

title: Cost-Aware Resource Management for Decentralized Internet Services
abstract: Decentralized network services, such as naming systems, content distribution networks, and publish-subscribe systems, play an increasingly critical role and are required to provide high performance, low latency service, achieve high availability in the presence of network and node failures, and handle a large volume of users. Judicious utilization of expensive system resources, such as memory space, network bandwidth, and number of machines, is fundamental to achieving the above properties. Yet, current network services typically rely on less-informed, heuristic-based techniques to manage scarce resources, and often fall short of expectations.

This thesis presents a principled approach for building high performance, robust, and scalable network services. The key contribution of this thesis is to show that resolving the fundamental cost-benefit tradeoff between resource consumption and performance through mathematical optimization is practical in large-scale distributed systems, and enables decentralized network services to meet efficiently system-wide performance goals. This thesis presents a practical approach for resource management in three stages: analytically model the cost-benefit tradeoff as a constrained optimization problem, determine a near-optimal resource allocation strategy on the fly, and enforce the derived strategy through light-weight, decentralized mechanisms. It builds on self-organizing structured overlays, which provide failure resilience and scalability, and complements them with stronger performance guarantees and robustness under sudden changes in workload. This work enables applications to meet system-wide performance targets, such as low average response times, high cache hit rates, and small update dissemination times with low resource consumption. Alternatively, applications can make the maximum use of available resources, such as storage and bandwidth, and derive large gains in performance.

I have implemented an extensible framework called Honeycomb to perform cost-aware resource management on structured overlays based on the above approach and built three critical network services using it. These services consist of a new name system for the Internet called CoDoNS that distributes data associated with domain names, an open-access content distribution network called CobWeb that caches web content for faster access by users, and an online information monitoring system called Corona that notifies users about changes to web pages. Simulations and performance measurements from a planetary-scale deployment show that these services provide unprecedented performance improvement over the current state of the art.

title: Improving fracture properties of MEMS components by surface control
abstract: This thesis studies the mechanical reliability of nanostructures. The strength statistics of Si nanobeams, their dependence on surface morphology and degradation due to air exposure are characterized and necessary conditions for maximum strength and durability are determined.

Due to their small sizes and use of low defect materials, nanostructures have the potential to be used in applications requiring very high stresses at low failure probabilities. Fracture strength of 190-nm thick Si beams have been shown to be as high as 13 GPa, approximately 30 times higher than the strength of macroscale samples. Testing similarly prepared beams etched with relatively smooth morphologies (0.4 nm rms) we showed that the strengths were further improved to 16 GPa, approaching theoretical strengths predicted by previous atomistic calculations.

To explain this influence, a series of fracture mechanics based Monte Carlo simulations were performed. Chemically modified surfaces of the tested beams were measured, statistically characterized and equivalent surfaces were generated. The surfaces consisted of bunched steps which act as stress concentrators, resulting in very high local stresses and hence enhancing material failure. Simulations of nanobeams processed using two different chemical etchants demonstrate the impact of surface morphology on fracture strengths characterized in terms of the Weibull distribution. It was shown that even a small increase in roughness reduces the strength considerably.

This high strength potential is promising for nanomechanical devices requiring high stress levels. Yet, for practical applications, maintenance of strength throughout the structure's service life may be as important as high initial strengths. Tests performed over a period of three weeks showed that this high strength degrades to 11 GPa when the beams are exposed to air. Coating the sample surfaces with protective methyl monolayers resulted in a 10\% higher initial mean strength, which was maintained throughout the test period under the same environmental conditions as the uncoated samples. Our results show that the strength degradation can be prevented by effective protection of surfaces.

The results of our experiments and simulations suggest that surface control is essential for the improvement and maintenance of high mechanical strengths at nanoscales.Cornell Center for Materials Research (CCMR), a Materials Research Science and Engineering Center of the National Science Foundation (DMR-0520404)

title: DEVELOPMENT OF A MODEL TO PREDICT EFFECTS OF MICROBIAL PREDATION ON LEAD PHASE DISTRIBUTION AND TOXICITY
abstract: Interactions between microbial predators and their prey can significantly influence the behavior of toxic trace metals. Metals associated with bacterial prey can be released into the dissolved phase following digestion by a predator, and/or metals can remain in the predator and potentially be transferred to the next level of the food chain. Toxic metal ions in the aqueous phase are also expected to modify the growth and predation rate of a microbial predator. A defined predator-prey system was developed to study metal behavior in simple microbial food chains using lead (Pb) as a representative metal. Desired features of this system were the ability to define the chemical speciation of dissolved metals as well as to distinguish between prey and predator-bound metals. Pseudomonas putida and the ciliate protozoan Tetrahymena thermophila were selected as representative bacterial prey and predator species, respectively. Batch reactors were used to measure

microbial growth parameters, effects of prey density on predation and Pb phase distribution. A mathematical model was developed to describe predator-prey dynamics and their influence on the behavior and fate of Pb. Growth data were used to obtain model parameters, and model simulations for Pb fractionation were compared to experimental observations.

The methodological studies demonstrated successful predator-prey separation techniques with little metal loss. Results of batch reactor experiments demonstrated that some kinetic parameters related to prey consumption and growth of T. thermophila are altered by Pb. Upon addition of predator to prey cells in equilibrium with dissolved Pb, dissolved and prey-bound Pb became associated with the predator through ingestion and adsorption. Ingested Pb was later excreted as a bound metal associated with T. thermophila waste matter. Experimental observations that did not match model predictions prompted further mathematical modeling of this predator-prey system. These simulations also explored Pb behavior under other hypothetical experimental conditions such as a chemostat reactor and a pulsed Pb dosing regime. The generality of the model was demonstrated by matching the trends in experimental data reported by other investigators for a different trace metal (Cd) in a different predator-prey system.

title: Structure-Property Relations in Bubble and Solid Particle Suspensions with Moderate Reynolds Numbers
abstract: In this study, several important properties of inertial bubble and solid particle suspensions have been characterized using numerical simulations. These properties include the hindered settling velocity and microstructure in solid particle suspensions, the scaling of the
velocity variance and hydrodynamic diffusivity in solid particle suspensions, the hindered rise velocity and microstructure in suspensions of monodisperse, spherical, non-coalescing bubbles, and the lift force on bubbles in a sheared suspension. In order to simulate suspensions of monodisperse, spherical, non-coalescing bubbles, a lattice-Boltzmann boundary rule was designed. On the last subject, the lift force in a sheared suspension, experiments have also been conducted to verify the simulations.

title: TEST ITEM CONSTRUCTION AND VALIDATION: DEVELOPING A STATEWIDE ASSESSMENT FOR AGRICULTURAL SCIENCE EDUCATION
abstract: In 2001, the New York State Board of Regents approved the New York State Regents Career and Technical Education Policy. Through the process of program approval, career and technical education (CTE) programs can provide students greater flexibility in attaining graduation credits in the areas of math, science, English and/or social studies for students completing such programs. The policy also states that individual career and technical completers can receive a technical endorsement on their Regents diploma. Part of the process for CTE program approval is to administer a technical assessment certifying that students meet current industry standards.

The impetus for this study was addressing the need of one secondary career and technical education program, agricultural science education, which does not have a statewide exam. Currently, the Department of Education at Cornell University in collaboration with New York Agricultural Education Outreach is in the process of developing a statewide exam for use as the technical assessment to certify students. Once approved, this exam will meet the technical assessment requirement for program approval. This study focuses on the

written multiple-choice portion of the statewide exam, specifically two aspects of developing an exam, item construction and item validation. Based on criterion-referenced test construction procedures two of the nine sections of the exam were developed, animal systems and plant systems.
The results of this study outline a process for developing and validating items. They highlight some of the benefits and disadvantages faced when developing test items for a diverse audience without the aid of a testing institute. Further consideration is given to procedures used to validate test items, specifically expert judgment and analytical data. The results from this study provide guidance to test developers related to aligning items to content, writing and editing items, and revising items.

title: Common Poisonous Plants
abstract: Poisonous plants are found everywhere. This bulletin, which includes color photographs, tells how to recognize the most common ones, how to avoid them, and what to do if a poisoning occurs. More than 40 species are described and illustrated. Poisonous cultivated house plants, flower and vegetable garden plants and ornamentals, as well as toxic wild plants are covered. Pet owners, parents, and farmers will find this information particularly useful.

title: Parenting Skills Workshop Series
abstract: This workshop manual is designed for professionals working with parents who may not learn well from text-based teaching approaches. Basic parenting skills are presented in a hands-on learning format suitable for any level of literacy. Originally designed for court-mandated parents, this workshop has proved successful with a broad audience.
The eight-week curriculum is based on themes consistent with familiar parent education programs such as STEP (Systematic Training and Effective Parenting), and PET (Parent Effectiveness Training). Each two-hour workshop becomes a setting for participants to learn new skills in a format that emphasizes action in "real" situations. "Five Basic Parenting Skills" posters and reproducible handouts, as well as a reproducible "Certificate of Achievement" included.

title: Your Septic System
abstract: Studying up on septic systems often ranks last in importance with homeowners - until an emergency strikes. This cleverly designed fact sheet set not only describes what to do if your septic system fails, but also contains all the necessary information to understand how a septic system works, how to properly maintain a septic system ? to prevent emergencies, and how to keep maintenance records ? all in a tidy, clearly marked and easy to find, tabbed folder that fits in a filing cabinet or notebook.
This resource is inexpensive, informative, practical, and it supports the concept and value of clean water quality standards and human health. A septic system is a critical component of a home, treating liquid waste in order to prevent contamination of drinking water and nearby lakes and streams.
The folder itself not only acts as an organizational device to hold vital septic system information, but also doubles as a quick-tip guide, and a maintenance record worksheet. Each of the five fact sheets inside the folder speaks to a unique topic revolving around septic systems. Fact Sheet #1, titled "What to Do if Your Septic System Fails", describes what a failure is, why failures happen, symptoms of a failure, immediate steps to take in case of a failure, long-term options, and prevention tips. Fact Sheet #2, "Maintaining Your Septic System: Special Considerations for Shoreline Property Owners" addresses unique issues associated with homes built near lakes, streams, or ponds, including how to identify signs that contaminants are reaching the water, and how to prevent problems. Fact Sheet #3, "How to Conserve Water in Your Home and Yard" offers 17 water saving tips that help reduce the risk of damaging your septic system, while saving money and protecting your health. Fact Sheet #4, "What You Need to Know When Buying or Selling a House" provides a list and description of minimum evaluation criteria, as well as an easy-to-use worksheet to aid in your home-buying or selling decision. Fact Sheet #5, "Considerations When Building or Remodeling a Home" covers siting your septic system, codes and permits, percolation tests, design and installation, and also includes a handy table for determining minimum septic tank capacities.
"Your Septic System" was developed by Cornell Cooperative Extension Project Team members Martha G. Shortlidge, Westchester County; Jo Ellen Saumier, Rockland County; Marjorie L. Nichols Keith, Putnam County; and A. Meyer, Dutchess County; and supported by a grant from the Water Resources Institute at Cornell University, with funds provided from the NYS Department of Agriculture and Markets. Some portion of the information contained in these facts sheets was adapted from Michigan State University Cooperative Extension Service.

title: utrient Bioavailability of Anthropogenic Dark Earth Soils and Surrounding Soils of Central Amazonian
abstract: A greenhouse experiment was carried out at the National Institute for Amazon Research, Manaus, AM, Brazil, to evaluate the nutrient bioavailability of Anthropogenic Dark Earth Soils and surrounding soils. Maize (Zea maiz L.) was planted in pots with two kg of air-dried soil to determine the relative fertility of the Dark Earth Soil and surrounding soil (Oxisol). Soil samples of surface layer (0-20 cm) was collected of four sites (Laranjal farm, A?utuba farm, Jiquitaia farm, Hatahara farm) and two soils per site (Dark Earth Soil

and Oxisols) following a randomized factorial design (4X2) with 8 treatments and eight replication, totals 64 pots. Half the pots were watered with distilled water to field capacity as required. The other half was watered with a minus-P nutrient solution to field capacity as required. The nutrient solution was applied to supply nutrients minus P, giving a bioassay of P bioavailability for the different soil locations and depths. Entire plants were harvested at the end of 2 months and total dry matter of shoots, roots and total nutrients uptake by plant were measured. Additionally soil fertility variability and phosphorus fractionation was done after maize was harvested. The results showed that Dark Earth soils are inherently more fertile by contrasting the growth and nutrient accumulation in the water-only-pots. Dark earth soil phosphorus availability from A?utuba ranged from 236 mg kg-1 (minus nutrient solution treatment) to 227 mg kg-1 (treatment with nutrient solution); dark earth soil phosphorus availability from Rio Preto da Eva ranged from 284 mg kg-1 (minus nutrient solution treatment) to 189 mg kg-1 (treatment with nutrient solution) and dark earth soil phosphorus availability from Laranjal ranged from 367 mg kg-1 (minus nutrient solution treatment) to 305 mg kg-1 (treatment with nutrient solution). The total phosphorus in the shoots showed a slight decrease with all treatments with dark earth soil plus nutrient solution. The treatments with dark earth soil plus nutrient solution showed that the phosphorus amount in the shoots ranged from 3, 11 to 3, 79 g kg-1. On the other hand, the same treatment minus nutrient solution showed that the phosphorus concentration in shoots ranged from 3, 43 to 4, 92 g kg-1. The treatments with surrounding soil plus nutrient solution showed that the phosphorus amount in the shoots ranged from 0, 92 to 3, 01 g kg-1. On the other hand, the same treatment minus nutrient solution showed that shoots phosphorus concentration ranged from 1, 30 to 3, 86 g kg-1. The higher increment of biomass was got to dark earth soil plus nutrient solution ranged from 9,56 g/pot (minus nutrient solution) to 26,13 g/pot (plus nutrient solution), an increment of 273%. All dark earth soil treatment presented low amounts of exchangeable potassium, ranged from 0, 05 Cmolc kg-1 to 0, 14 Cmolc kg-1, after maize was harvested. Based on preliminary results presented above, we propose that the natural fertility of the Dark Earth Soil is relative since low levels of potassium are a restriction to crop growing. Not only the surrounding soils but also the dark earth soils in all sites presented aluminium phosphate plus iron phosphate higher than 65% of the total phosphorus pool, except the dark earth soil from the Hatahara farm that showed calcium phosphate higher then 60% of the total phosphorus pool.

title: Exploring Atypical Stabilization Pathways Using Pool-Based Modeling
abstract: Simulation models that explicitly account for the impact and interaction of soil and environmental variables can assist in predicting the accumulation of C and its rate of turnover. Relevant, verifiable (i.e. measurable) pools of Soil Organic Matter (SOM) provide the most robust basis for elucidating the underlying mechanisms. We have developed a model based around three measurable pools of SOM which can be measured using a density-based fractionation procedure, and verified by extensive chemical characterization. The model has been optimized against measurements of C and N and isotope-tracers in several soils amended with isotope-labeled organic matter. According to recent estimates black C is a much larger component of Soil Organic Carbon (SOC) in typical agricultural soils than previously assumed. Since black C may also be the most stable form of organic C in the soil, the amount of black C in the soil must impact both on the bulk rate of soil C mineralization (turnover) and the extent to which a particular management intervention can alter SOC. Until now our simulations have not accounted explicitly for the effect of black C on the dynamics of each pool. We are now examining how black C is characterized by physical location within the soil matrix, and in order to account for the influence of black C using this model affects C mineralization, and the distribution of charcoal between each of the measured fractions.

title: Black Carbon from Rice Residues as Soil Amendment and for Carbon Sequestration
abstract: On highly weathered soils in tropical and subtropical climates, maintenance of soil organic matter is essential to sustain system productivity and avoid rapid soil degradation. But climatic conditions as well as soil characteristics favor the rapid decomposition of organic matter. However, several recent studies indicated that black carbon, the product of incomplete combustion of organic material, could combine characteristics highly beneficial for soil nutrient dynamics with high stability against chemical and microbial breakdown. Lasting soil amelioration by incorporation of black carbon from wooden plants was proposed based on the beneficial evidence from ?Terra Preta? soils in Western Amazonia. Theoretically, charred crop residues in rice-based systems could serve the same purpose but this hypothesis has never been tested. Within this context, our objectives were to 1) assess possible options for the use of charred rice residues, to 2) test the effect of charred rice residues on important soil fertility parameters and rice growth, and 3) to evaluate the effect and stability of charred rice residues in a variety of rice growing environments. Initial investigations showed that charred rice husks are already used in several Asian countries, e.g. in Japan for seed bed preparation of rice and vegetable crops, and in the Philippines for soil amelioration in ornamental plant production. Charring of rice husks in Japan is known as ?Kuntan? and simple techniques for its production are even part of agricultural training courses. First experiments showed that charring rice husks slightly increases the relative carbon content but the weight loss from fresh to charred rice husks is about 70%. Similarly to carbon, the relative concentration of other nutrient elements (e.g., N, P, K, Ca, Mg) is maintained or even increased. Greenhouse studies in pot experiments conducted in the Philippines and northeast Thailand in 2005 showed positive effects of charred rice husks on rice biomass, rice yield, and cation exchange capacity. No increased leaching of organic carbon was observed when charred rice husks were added to the soil. Randomized and replicated field trials including control treatments and +/- inorganic fertilizer treatments were established in a variety of rice-growing environments including irrigated lowlands, rainfed uplands (both in the Philippines), rainfed lowlands (northeast Thailand), and the rice-wheat system (India). In these trials, the quantity of carbon applied equaled about 1.4% in the surface soil layer (0.0 - 0.1 m) or about 16 t carbon per hectare. Converted to biomass, this is equivalent to the crop residues of about 10 to 20 seasons, depending on the system's productivity (including straw and assuming the above mentioned efficiency in black carbon production). In the first cropping season, observed agronomic effects of the charred rice husks were variable and depended on the cropping system and the indigenous soil fertility. Contrary to that, the effects on soil characteristics were more consistent and major effects were an increase of the cation exchange capacity, a decrease of soil bulk density, and a stable increase of soil organic carbon. However, preliminary results strongly suggest that a continuation of the field trials is necessary to better evaluate the long-term treatment effects. If the greater part of the applied black carbon proves to be stable in some or all tested cropping systems, this technology could be an interesting option for carbon sequestration. If used at a large scale, considerable research efforts would be needed to evaluate the various and far-reaching consequences of the proposed technology.

title: Optimization for Bursting Neural Models
abstract: Advisor: John Guckenheimer,
Committee Members: Lars Wahlbin, Ron Harris-WarrickThis thesis concerns parameter estimation for

bursting neural models. Parameter estimation for differential equations is a difficult task due to complicated objective function landscapes and numerical challenges. These difficulties are particularly salient in bursting models and other multiple time scale systems. Here we make use of the geometry underlying bursting by introducing defining equations for burst initiation and termination. Fitting the timing of these burst events simplifies objective function landscapes considerably. We combine this with automatic differentiation to accurately compute gradients for these burst events, and implement these features using standard unconstrained optimization algorithms. We use trajectories from a minimal spiking model and the Hindmarsh-Rose equations as test problems, and bursting respiratory neurons in the preBotzinger complex as an application. These geometrical ideas and numerical improvements significantly enhance algorithm performance. Excellent fits are obtained to the preBotzinger data both in control conditions and when the neuromodulator norepinephrine is added. The results suggest different possible neuromodulatory mechanisms, and help analyze the roles of different currents in shaping burst duration and period.

title: A Method to Remove Fringes from Images using Wavelets (with IDL's defringeflat v1.5.5)
abstract: Check for the most recent release of the accompanying software at: http://www.das.uchile.cl/~pato/sw/We have developed a new method that uses wavelet analysis to remove interference fringe patterns from images. This method is particularly useful for flat fields in the common case where fringes vary between the calibration and object data. We analyze the efficacy of this method by creating fake flats with fictitious fringes and removing the fringes. We find that the method removes 90% of the fringe pattern if its amplitude is equal to the random noise level and 60% if the fringe amplitude is ~1/10 of the noise level. We also present examples using real flat-field frames. Version 1.5.5 of a routine written in IDL that implements this algorithm is available from the authors and as an attachment to this paper.The National Aeronautics and Space Administration under grant NAG5-13154 issued through the Science Mission Directorate.

title: Biologically Active Natural Products from Plants and Their Endophytes
abstract: Plants and the fungi that colonize them (endophytic fungi) are prolific producers of the kinds of structurally interesting and biologically active small molecules (natural products) that captivate chemists and biologists alike. The work reported here focuses on the isolation of new natural products by two different yet complementary strategies. In the first, we sought new chemical diversity from a largely unexplored pool of biodiversity - the endophytic fungi. In the second, we examined a well-studied natural product reservoir - traditional Chinese medicinal plants - using new and innovative biological screens at the Institute of Chemistry and Cell Biology at Harvard Medical School.

The isolation and structure determination of a new inhibitor of STAT3 signaling from the Floridian endophytic fungus FA39 is described. FA39 showed 97% rDNA sequence identity to the ascomycete Phaeosphaeria avenaria. Bioassay-guided fractionation of FA39 yielded the STAT3 inhibitor phaeosphaeride A, and its inactive diastereomer phaeosphaeride B.

The discovery of a new family of non-templated biopolyesters from the Costa Rican endophytic fungus CR873 is described. CR873 showed 99% rDNA sequence identity to the ascomycete Daldinia concentrica. This fungus produces large amounts of oligomers of (3R,5R)-3,5-dihydroxyhexanoic acid - the first example of a eukaryote that produces biopolyesters of this nature.

The isolation and structure elucidation of two new cytokinesis-inhibitory cucurbitacins using a fluorescence imaging screen is described. The new cucurbitacins were isolated from Physocarpus capitatus along with a new biphenyl and the known compounds cucurbitacin F and 23,24-dihydrocucurbitacin F. Studies into the mechanism of action of the cucurbitacins are also reported.

The isolation and structure elucidation of TRPV4 channel activators and the structure elucidation of an angiogenesis inhibitor from prefractionated traditional Chinese medicinal plants are described. TRPV4 activators kaikasaponin III from Sophora sp. and linoleic acid from Stellaria sp. and Fritillaria sp. were identified without any further chromatographic separation. The diterpene dimer bisandrographolide A was isolated from Andrographis sp. after a single round of HPLC and found to potently activate TRPV4 channels. Hydroferulic acid from Stellaria sp. was identified in a screen of angiogenesis inhibitors without any further chromatographic separation. Attempts to optimize the activity of hydroferulic acid are also described.NSF Graduate Research Fellowship; NIH-NCDDG grant (CA67786); NIH-Starr Foundation grant (R21AT001979); NIH grant (CA24487)

title: The Weather Around Black Holes: Accretion Disk and Jet Evolution in GRS 1915+105 and Other Systems
abstract: Ph.D. dissertation, Cornell University, Department of Astronomy. Faculty members supervising this work included Richard Lovelace (chair), Steve Eikenberry, Jim Cordes and Dong Lai.A fundamental problem in astrophysics involves the origin of jets and the dynamics of accretion disks. How does a collimated outflow arise from hot material that is spiraling into a central object (be it a black hole, neutron star, white dwarf or young star)? Why do jets appear to turn "on" and "off" as the accretion disk changes between different states?

In this thesis, we attempt to shed some light on this question through observational, theoretical and computational studies. We present high time resolution observations of the Galactic black hole candidate GRS 1915+105 and show how subtle differences in the accretion disk evolution in this object during different episodes of activity are related to different types of jet ejections. We then develop several new theoretical results about accretion disks that allow us to parametrize our uncertainty about the jet and other complex physics in a way that can be studied in one- or two-dimensional numerical simulations. Following this, we present FRIENDLY, a new code for numerical integration of arbitrary partial differential equations to arbitrary orders of accuracy that was developed during the course of this thesis. Finally, we present a preliminary application of FRIENDLY, in which we attempt to simulate an accretion disk that experiences a sudden increase in the strength of turbulence, as might be expected if an ordered magnetic field were ejected from the system in the form of a jet. We compare the simulations to the observations of GRS 1915+105 and conclude that further study of this mechanism may lead to an explanation for the behavior of this enigmatic object.Much of the material in this thesis is based upon work supported under a National Science Foundation Graduate Research Fellowship. Additional support came from NSF CAREER award NSF-9983830, the Cornell Science Inquiry Partnerships (CSIP) program at Cornell (a National Science Foundation Graduate Teaching Fellows in K-12 Education program), the NASA Space Grant program, and the Stewardship Sciences Academic Alliances program of the National Nuclear Security Administration under US Department of Energy Cooperative agreement DE-FC03-02NA00057.

title: Characterizing the Interplay between FAK, Src, and ACK2 in the Regulation of SH3PX1 Activity
abstract: Sorting nexin, SH3PX1, has been associated with endocytosis through its interactions with key endocytic proteins involved in the processing of cell surface receptors. These dramatic cellular effects, largely associated with the tyrosine phosphorylation of SH3PX1, have elicited interest in determining the molecular mechanisms underlying this phosphorylation event.

The first major focus of these studies was to develop reagents that could be used to further characterize the role of SH3PX1 in endocytosis. SH3PX1 has been identified as a substrate of the nonreceptor tyrosine kinase, activated Cdc42-associated kinase-2 (ACK2), and the resulting phosphorylation enhances degradation of the epidermal growth factor (EGF) receptor in cells. In order to further characterize ACK2-catalyzed SH3PX1 phosphorylation, we have identified tyrosine 287 as a major site of phosphorylation by mass spectrometry. Moreover, we have shown that the pyridopyrimidine PD158780 is a potent inhibitor of ACK2 kinase activity in vitro (IC50 ~80 pM). Together, we believe that phosphorylation-defective mutants of SH3PX1 and small molecule inhibitors of ACK2 kinase activity will help to further establish the roles of ACK2 and SH3PX1 in EGF receptor processing.

The second aspect of these studies involved the identification and characterization of novel tyrosine kinases that phosphorylate SH3PX1 in cells, namely focal adhesion kinase (FAK) and Src. Here, we show that FAK and Src differ considerably from ACK2 in their abilities to phosphorylate SH3PX1. For example, FAK and Src are more effective kinases for SH3PX1, compared to ACK2. In addition, we show that FAK and Src are able to phosphorylate several carboxyl-terminal truncation mutants of SH3PX1 that are defective for ACK2-catalyzed phosphorylation, suggesting that FAK and Src bind to and phosphorylate different sites on SH3PX1. This was further confirmed by mass spectrometry analysis which identified residues Y177, Y239, Y269, Y294, and Y561, as Src-catalyzed phosphorylation sites, with Y239 as the major site. Given the observed differences exhibited by FAK and Src, versus ACK2, in binding and phosphorylating SH3PX1, it now seems likely that this sorting nexin may be responsible for translating a complicated array of regulatory inputs into the endocytosis and degradation of membrane receptors.

title: Transit Spectroscopy of the Extrasolar Planet HD209458b: The Search for Water
abstract: === Committee members === Chair: Peter Gierasch.
Member: Joseph Harrington (advisor). Minor Member: Warren Allmon. Field Appointed Member: Donald Campbell.This dissertation describes an attempt to detect water in the atmosphere of the extrasolar planet HD209458b using transit spectroscopy. It first discusses the importance of water detection and reviews the state of knowledge about extrasolar planets. This review discusses the main statistical trends and describes the detection methods employed to this date. The importance of the transiting planets and the many measurements of the known ones are also discussed.

A radiative transfer model designed and built specifically for this project predicts, given a planetary temperature/pressure/composition profile, the dependence in wavelength of the stellar spectrum modulation due to a transiting planet. A total of 352 spectra around 1.8 microns were obtained on four nights (three in transit) of observations on August 3--4, September 26, and October 3 of 2002 using ISAAC at the Very Large Telescope.

Correlating the modeled modulation with the infrared spectra yields a non-detection of water in the atmosphere of \hdt. It is found that the non-detection is due to an unfortunate choice of observing parameters and conditions that made it impossible to reach the required sensitivity. Nonetheless, the results are scaled with synthetic spectra to place strong limits on the planetary system configurations for which the observing parameters and telluric conditions would have yielded a successful detection. None of the 10 other known transiting planets would be detectable with the choice of parameters and conditions for this observation.

A quantitative model of an improved observing strategy for future observations of this kind is developed. The improvements include: airmass and timing constraints, the simultaneous observation of a calibrator star, and a new method to find the optimal wavelength range.

The data-reduction process includes several original techniques that were developed during this work, such as a method to remove fringes from flat fields and several methods to correct for telluric absorption, among others.

Some of the code developed for this project is available under the GNU General Public License at the DSpace Internet archive from Cornell University.The National Aeronautics and Space Administration under grant NAG5-13154 issued through the Science Mission Directorate.

title: OBSERVATIONS OF THE MARTIAN ATMOSPHERE: THEMIS-VIS CALIBRATION, MESOSPHERIC CLOUDS, AND THE POLAR VORTEX
abstract: We present observations of the Martian atmosphere derived from two instruments: the Thermal Emission Spectrometer (TES) on the Mars Global Surveyor space-craft, and the visible light subsystem of the Thermal Emission Imaging System (THEMIS-VIS) on the Mars Odyssey spacecraft. For TES, we start with vertically resolved temperatures derived as described by Conrath et al. (2000, JGR, 105), and from them we derive horizontal winds and Ertel potential vorticity on a time series of regular three-dimensional grids. The Ertel potential vorticity is used as a dynamical tracer and diagnostic tool to study the behavior of the martian polar vortices. We find that, in contrast to the terrestrial polar vortices, the martian polar vortices? Ertel potential vorticity typically has an annular maximum well away from the pole. We also find that the martian northern winter vortex is better organized than the southern winter vortex, and thus is likely to be a more effective barrier to mixing. For THEMIS-VIS we develop a complete radiometric calibration pipeline. This pipeline is used for standard data processing to convert Engineering Data Records (EDRs) to the Reduced Data Records (RDRs) released by NASAs Planetary Data System. We use THEMIS-VIS nadir-pointed images to detect clouds in the 40 km to 80 km altitude range, measuring altitude from parallax and velocity fromcross-track motion during the imaging sequence. We have observed 5 cases of aphelion season equatorial high-altitude clouds during late afternoon, all located in the eastern Tharsis / Valles Marineris region, and 30 cases of high-altitude cloud features in the northern winter (perihelion season) mid-latitudes, all but one in the Acidalia region. A simple radiative transfer model yields optical depths greater than 0.2 for the equatorial clouds, as well as constraints on their composition. The mid-latitude high-altitude features are visible only in twilight, a geometry for which our simple plane parallel radiative transfer model is not valid. Comparing the zonal velocity of the clouds with a radiative transfer model, we find good agreement in the northern winter mid-latitudes, but poorer agreement for equatorial clouds.

title: Universality in Multiparameter Fitting: Sloppy Models
abstract: In order to understand a variety of physical phenomena (such as signaling networks in molecular biology or crystal structures in condensed matter physics), scientists often develop models with many unknown or tunable parameters. Such multi-parameter models and systems are often sloppy. For practical purposes their behavior depends only on a few stiffly constrained combinations of parameters; other directions in parameter space can change by orders of magnitude without significantly changing the behavior. We develop the theoretical basis of sloppiness and argue that there is in fact a new universality class to which these models belong.

We begin by defining sloppiness (an exponentially large range of sensitivity to different combinations of parameters, with a roughly uniform distribution of sensitivities between the extremes). We then document sloppiness in a variety of models from different scientific fields. Several mathematically well-defined classes of models, some sloppy and some not sloppy, are then analyzed to understand the origins of sloppiness. Drawing connections to the field of random matrix theory, we derive an ensemble of sloppy models. The heart of sloppiness in this ensemble is shown to be the Vandermonde matrix. By demonstrating the novel statistical properties of this ensemble we argue that it constitutes a new universality class. Inspired by the properties of this Vandermonde ensemble we develop new tools for analyzing complex, real-world models with many parameters.

In the final section we focus on a particular complex, real-world model with many parameters. We formulate and analyze a mathematical description of the quorum sensing network in the bacterium Agrobacterium

tumefaciens. This network allows Agrobacterium to regulate gene expression in accordance with its population density. The mathematical description includes twenty four unknown parameters quantifying the biochemical interactions. While not complete, the model provides insight into the quorum sensing process and we suggest ways of coupling the model with experiments in the future.

title: Being a Librarian
abstract: This presentation was adapted from a Taiga Forum http://www.taigaforum.org/ presentation made in March 2006Librarians have perhaps taken the most pride in their role as intermediaries, whether as reference librarians personally connecting users to the information they need, or as the creators of tools, like library catalogs, that facilitate those connections. However, in the interconnected world of the Web, information seekers behave more and more self-sufficiently, choosing simple but powerful search engines and moving well beyond catalogs and library collections in their pursuit of information. Using her recent research on the integration of the catalog with other discovery tools as a starting point, Calhoun will explore how librarians can continue advancing the state of knowledge in a digital world.

title: Libraries as Distributors of Geospatial Data: Data Management Policies as Tools for Managing Partnerships
abstract: Libraries can bring substantial expertise to bear on the collection, curation, and distribution of digital geospatial information, making them trusted and competent partners for organizations that wish to distribute geospatial data. By developing a well-thought-out data management and distribution policy, libraries can define the parameters of a data distribution partnership and reinforce a data provider's confidence in the library's role as a data custodian and distributor. In developing a policy, data distributors are advised to consider such issues as intellectual property rights, liability issues, distribution methods and services, data and metadata management practices, security risks posed by geospatial data, and user limitations. This article describes the most common elements of data sharing and distribution agreements and describes the development of a data management policy for the Cornell University Geospatial Information Repository (CUGIR).

title: Guide to the Plant Communities of the Central Finger Lakes Region
abstract: This book is for anyone with an interest in the outdoors, who would like to learn about the Finger Lakes region in general, and in particular about the kinds of plant communities found in central New York. Our main objective is to provide an introduction to the major types of plant communities in the region and where in the landscape they occur. It is intended to be read as a normal book, from beginning to end; it can also be used as a reference to be consulted about the nature of a particular community type. The book is written primarily for those without a background in botany or plant ecology, but should also be of interest to naturalists and biologists.

title: The Cornell Guide for Planting and Maintaining Trees and Shrubs
abstract: The Cornell Guide for Planting and Maintaining Trees and Shrubs is a benchmark text written for professional horticulturists and home owners alike.
Includes reliable tips for properly selecting plants from nurseries, guidance for appropriate site selection, transplanting processes and schedules, drainage management, and soil preparation. Important tasks immediately following planting - from watering, mulching, staking and wrapping, to pruning, fertilizing and anti-desiccant application provide professionals and hobbyists with knowledge to ensure their trees and shrubs flourish and thrive. Regular maintenance practices, including tips for protecting plants during construction, and the importance of monitoring for insect and disease problems are included. Includes numerous drawings, tables, tips, historical references, and a glossary with important terms.

title: PruningAn Illustrated Guide to Pruning Ornamental Trees and Shrubs
abstract: This pruning guide offers practical information, with clear, easy to follow instructions for successful pruning and maintenance of ornamental trees and shrubs. Readers begin with the basics of timing and frequency of pruning, and the necessary equipment to achieve the desired results. Gardeners and landscapers will find detailed instructions for pruning, maintaining, and rejuvenating deciduous and evergreen trees, shrubs, heaths and heathers. A section is devoted to manipulation techniques for shaping shrubs into small trees, as well as configuring hedges and vines. Topiary, pollarding, espalier and chemical growth control instruction is included for advanced gardeners. Numerous drawings, tables, tips, historical references, and the glossary are included in the bulletin which is drawn from Cornell research, extension demonstrations, and practical landscape and garden experience.

title: Lawn Care Without Pesticides
abstract: This text focuses on reducing environmental stressors on grass plants as the key to a lush, beautiful, and thriving lawn. This bulletin teaches how grass grows and why lawns matter, and suggests ways to reduce stress. Following the steps in this bulletin can cause the home lawn to grow stronger, and be more resistant to weeds, insects and diseases.
Lawn Care without Pesticides begins with a 7-step, first-year plan. The publication covers how grass grows, best mowing, watering & fertilizing practices, how to repair small bare spots, renovating and establishing lawns, choosing lawn grasses, relieving thatch, coping with shade, and dealing with salt damage. During the first-year this bulletin teaches the user to gather information about the lawn: Test the soil, observe soil conditions, watch the sun, and note high-traffic areas. This publication has helpful diagrams and tables throughout.

title: Liquid-on-liquid mixing for slide-based biological assays
abstract: Many parallel biochemical assays rely on thin aqueous films to spread a reactant solution over a wide area decorated with multiple distinct substrates. In this asymmetric, microfluidic geometry, diffusion limits the transport of reactants to substrates. Chemical equilibrium, a requirement for reproducibility of results, can take days to achieve.

The liquid-on-liquid mixing (LOLM) method overcomes the diffusion barrier by layering an immiscible spectator fluid, such as mineral oil, on the thin film. Stirring the spectator fluid transmits shear at the liquid-liquid interface into the thin film. The mixing accelerates the march towards equilibrium. This technique increases the speed and sensitivity of immunofluorescence staining of Drosophila larval polytene chromosomes by a factor of 100 in time and concentration, when compared to standard coverslip techniques.

Flow visualization experiments reveal the fluid motions in the thin aqueous layer. Using time-lapse video photography to monitor the evolution of a drop of colloidal dye in the thin film, I estimate the time needed to achieve good mixing at various stir rates.

The major aim of this technique is improving the hybridization step in DNA microarrays. I printed microarrays and subjected them to hybridizations with varying stir rates, durations, and target DNA concentrations. My data suggest that the mixing produces at best a modest improvement in efficiency, uniformity, sensitivity, and specificity when compared to microarrays incubated with the standard coverslip method.This work was supported by the Cornell University Center for Biotechnology, a New York State Center for Advanced Technology, supported by the New York State Office for Science, Technology, and Academic Research and industrial sponsors. This material is based upon work supported in part by the STC Program of the National Science Foundation under Agreement No. ECS-9876771, through the Cornell Nanobiotechnology Center (NBTC). title: Mesoscale Theory of Grains and Cells: Polycrystals & Plasticity
abstract: Solids with spatial variations in the crystalline axes naturally evolve into cells or grains separated by sharp walls. Such variations are mathematically described using the Nye dislocation density tensor. At high temperatures, polycrystalline grains form from the melt and coarsen with time; the dislocations can both climb and glide. At low temperatures under shear the dislocations (which allow only glide) form into cell structures. While both the microscopic laws of dislocation motion and the macroscopic laws of coarsening and plastic deformation are well studied, we hitherto have had no simple, continuum explanation for the evolution of dislocations into sharp walls. We present here a mesoscale theory of dislocation motion. It provides a quantitative description of deformation and rotation, grounded in a microscopic order parameter field exhibiting the topologically conserved quantities. The current of the Nye dislocation density tensor

is derived from downhill motion driven by the microscopic Peach--Koehler forces between dislocations, making use of a simple closure approximation. The resulting theory is shown to form sharp dislocation walls in finite time mathematically described by Burgers equation---similar to those seen in the theory of sonic booms and traffic jams. Our finite-difference methods use special upwind and Fourier techniques for dealing with the shock formation. The outcomes of our simulations in one and two dimensions are in good agreement with experiment and other discrete dislocation simulations. These results provide fundamental insights into the basic phenomena of plastic deformation in crystals, and offers predictions for residual stress, cell-structure refinement, and the distinguish features of different hardening stages in plastic deformation.

title: Neighbors Building Neighborhoods: A Critical Look at Citizen Participation in Rochester
abstract: In the last several decades, there has been a shift away from the central planning model in America. Reactions from the grassroots have emerged as citizens strive to address urban needs independently of planning bodies. However, many would argue that this is not the answer either.

Planning at the level of urban administration currently coexists in tension with planning at the grassroots level. Planning from the top is attempting to be more attentive to needs in the neighborhoods, as citizens have begun to acquire the energy and resources to lobby for change. Oftentimes, government-grassroots partnerships are forged to exploit the capacities of both entities in planning endeavors. However, this leads to the question of how this tension creates opportunities for improvements of social conditions, whether it contributes to the larger vision of enlarging the political capacity of a society, and which is the appropriate body to make a plan and implement it.

A government-grassroots partnership was attempted in the City of Rochester, through the Neighbors Building Neighborhoods (NBN) program. The year 2006 marks the 13th year of the program. After 13 years of negotiations, consultation, community meetings, conflict, and lobbying, numerous milestones have been achieved. Through NBN, hundreds of neighborhood projects have come to fruition, while many others have broken ground. These projects include physical improvements, beautification projects, the construction of new schools and stores, better public services, and increased public safety measures. NBN also received awards for its successful neighborhood revitalization efforts, and is recognized as a model of best practices.

Many people in Rochester are happy with the achievements made through NBN. However, some believe that the process can be further modified for greater success. The recent election of a new mayor into the Rochester City administration has resulted in some uncertainty in the future of NBN ? will the process continue as it, be modified, or go down in history as a pet project of the previous administration? This thesis

examines the NBN process to: 1. document the NBN process in Rochester an example of government-initiated grassroots-planning action that other city planning organizations can refer to; 2. place the era of NBN in the context of Rochester's history as a city of citizen action; and 3. explore NBN as Rochester's solution to the problem of the appropriate bodies to make a plan and implement it.Cornell Department of City and Regional Planning - Kermit C. title: FUNCTIONAL BLUEPRINTS: A DYNAMICAL APPROACH TO STRUCTURE REPRESENTATION
abstract: In engineering design, form has traditionally been specified explicitly using blueprints. This thesis explores an alternate way of specifying form built on interactions between dynamical systems. This alternate form specification is based on ideas from natural development. Inspired by termite nest building behavior, dynamic developmental systems are proposed as an alternate method to produce and represent structure designs, which when compared to the conventional blueprint method are a more robust form specification method, more adaptive, and even able to self-repair. Developmental systems are uses here as a method of form specification and an evolutionary algorithm is the method of design chosen to explore the capabilities of these developmental systems. Evolutionary algorithms have already been widely studied and proven to be an effective method of finding solutions to tough problems, and in this work they are simply a validated tool being used. The experiments included in this work use developmental systems with high degrees of system-environment interaction and show the importance of a subtle and often overlooked difference between two similar kinds of systems. An important distinction is being made between systems which both use feedback from the environment. These systems are referred to as the reactive system and the interactive system. The reactive systems simply use environment feedback during their development, whereas the interactive systems not only use environmental feedback but actually form a two-way dynamic feedback cycle WITH the environment. Our control experiments are the systems with one-way feedback which have a system-environment interaction level where the system uses information from the environment during its development but does not affect the environment?s dynamics. Our experiment systems ii use dynamic feedback, which allows them to affect the dynamics of the environment while simultaneously the environment reacts to this stimulus, forming a two-way feedback loop which makes the system more situated in the environment. The experiments in this thesis used the evolutionary algorithms to search for systems which fulfilled the desired effect on the environment. In this case this effect is to build a structure that causes the average temperature in the environment to come as close as possible to a target temperature, which is specified at the beginning of the evolutionary run. Both types of systems were evolved using evolutionary algorithms and those systems which used dynamic environmental feedback consistently displayed better performance.

title: Gender and Say: A Model of Household Behavior with Endogenously-determined Balance of Power
abstract: The evidence that the same total income can lead a household to choose different consumption vectors, depending on who brings in how much of the income, has led to an effort to replace the standard unitary model of the household with the ?collective model?, which recognizes that the husband and the wife may have different preferences and depending on the balance of power between them the household may choose differently. One weakness of this new literature is that it fails to recognize that the household?s choice could in turn influence the balance of power. Once this two-way relation between choice and power is recognized we, are forced to confront some new questions concerning how to model the household. This paper tries to answer these by defining a “household equilibrium”, examining its game-theoretic properties and drawing out its testable implications. It is shown, for instance, that a household equilibrium can be inefficient and that (for a certain class of parameters) children will be least likely to work in a household where power is evenly balanced. The paper also draws out the implications for female labor supply.

title: Racial Conflict and the Malignancy of Identity
abstract: This paper demonstrates how our sense of identity can emerge out of mere markers of social distinction that may have no innate significance, but, nevertheless, spread to various aspects of our lives and be the root of conflict. The basis of such conflicts could arise from the use of race to form conditional judgments about people?s behavior. Moreover, there are contexts where racial conflict is inevitable even though, if individuals had common knowledge of one another's preferences, there would be no conflict. It is argued that this kind of conflict, where many individuals have no innate aggressive preference, is widespread and understanding the process that gives rise to such conflict is the key to crafting effective policy that contains it.

title: The Economy and the Foundation of the Modern Body Politic: Malthus and Keynes as Political Philosophers
abstract: My dissertation explores the making of the modern division between the political and the economic realm. To modern political reason, the economy appears like a self-standing reality, internally related in terms of functions and understood to follow regulating laws of its own. The dissertation counters this account of the relation between the economic and the political realm. It analyzes the epistemological claims to objectivity, on which this division rests and shows how the allegedly neutral depictions of economic necessity remain inextricably linked to political imaginations of order. The main thesis of the work posits that the modern rendering of economic reality in terms of a self-contained and functional realm stems from the desire to establish secure foundations for a viable body politic.
The works of Malthus and Keynes are the exemplary cases for this study of the intimate relations between political reason and accounts of economic objectivity. The writings of Malthus crystallize in important respects the emergence of the specific modern objectivity at the beginning of the nineteenth century. With him, the notion of scarcity gained its important role for defining economy. It is shown that the definition of economy in terms of scarcity is tied to Malthus? attempts to envision a regulatory epistemology for the social body, which ensures a silent and visceral order against the uncertainties of the political world. The economic realm is thus conceived as the foundation of the body politic. The writings of Keynes witness the crisis of this economic foundation at the beginning of the twentieth century. The dissertation explicates Keynes' critique of the epistemology of scarcity, which underwrites modern accounts of economy. He opens a perspective on economy in terms of temporality, conventions and power, which traverses the closed boundaries of the economy. But this different view on economy is overlaid by Keynes' political desires to procure new foundations for the body politic: the envisioning of a national economy under the guidance of the economic expert, for which Keynesian economics is known, fulfills this desire. The thinking of economy is thus shown to be inextricably tied to the question of the political.

title: Design and calibration of optical tweezers for single-molecule studies

abstract: This version is a PDF produced from the source Microsoft Word document. Figure 13, on logical page 36 (PDF page 46), is missing. It was a CorelDraw drawing of the optical layout. Please see the supplemental files "20000710 tweezers1xx AI9.emf" and "20000710 tweezers1xx AI9.ai" for enhanced metafile and Adobe Illustrator 9 versions of that figure.Feedback-controlled optical tweezers are used to manipulate single biological molecules in experiments on deoxyribonucleic acid (DNA) substrates. Before we trust these measurements, it is essential to know the accuracy and the precision of the device. This thesis describes the design and calibration of the optical tweezers. We measure relative displacements with nanometer accuracy and forces with an accuracy of 10%. The chief source of imprecision is in the human positioning of the sample under study. The capability of the instrument is demonstrated by stretching single molecules of DNA because of the elasticity of DNA has previously been well characterized. This thesis also compares DNA elasticity measurements made on this device with previously published data. I demonstrate that this instrument is well suited for characterizing DNA molecules that are long (~ 4000 bp), but not for DNA that are relatively short (~ 1000 bp). Fit parameters for new DNA tethers containing 4400 base pairs (bp) of DNA agree with expected values. The optical tweezers instrument is accurate enough to determine that one-hour-old 4400-bp DNA tethers have degraded, losing some 4% of their length. Our current methods are not appropriate for measurements of force-extension of short DNA molecules, such as 1155-bp DNA tethers.This work was supported by NIH Molecular Biophysics Training Grant T32 GM08267 and grants to Michelle D. Wang from the NIH and from the Keck Foundation.

title: THE BENCHMARKED LINEARIZED EQUATIONS OF MOTION FOR AN IDEALIZED BICYCLE (IMPLEMENTED IN SOFTWARE AND DISTRIBUTED VIA THE INTERNET)
abstract: People have been successfully building and riding bicycles since the 1800s, and many attempts have been made to describe the motion of these machines mathematically. However, common acceptance of the correct linearized equations of motion for a bicycle has remained elusive. In his 1988 master?s thesis at Cornell University, Scott Hand derived the equations again and performed the first known extensive survey of the literature, finding and documenting the mistakes made in previous attempts. The question remained however of what mistakes, if any, Mr. Hand and his advisors made. The subsequent advent of cheap and plentiful computing power and the development of numerical methods to take advantage of it provide an opportunity to confirm, once and for all, the correct linearized equations of motion for an idealized bicycle. That is exactly what A. L. Schwab, J. P. Meijaard, and J. M. Papadopoulos have done in their recent paper. The next step is to efficiently promulgate these correct and confirmed equations in a useful form. The goal is that anyone working in the areas of bicycle or motorcycle handling or control can use these equations directly or verify their own underlying equations against this benchmark. This thesis describes a program, JBike6, its on-line help, and its web site designed specifically for that purpose: to provide a turn-key application for evaluating the self-stability of a bicycle. JBike6 also generates numbers (eigenvalues and matrix entries) that can be used to compare, to very high precision, against any other linearized or fully non-linear equations of motion for a bicycle. After a brief review of the application, theory, and results of JBike6, the contents of this thesis consist primarily of hard copy of the on-line help and web site and screen shots of the program. The text has been modified to be more readable as a narrative and some pictures have been formatted to fit within the margins. Obviously, the interactive nature of the program, the help file, and the web site, including the hyperlinks, animations, and videos, is not available in this printed document. While all the components will continue to evolve, this thesis is a snapshot of them in September 2006. Many redundancies have been removed, but some remain in order to preserve the integrity and flow of the individual components. All these components may currently be found on-line at www.tam.cornell.edu/~ad29/JBike6

title: Prediction and Optimal Experimental Design in Systems Biology Models
abstract: In this dissertation we propose some approaches in model-building and model analysis techniques that can be used for typical systems biology models.

In Chapter 2 we introduce a dynamical model for growth factor receptor signaling and down-regulation. We show how, by quantitatively fitting the model to experimental data, we can infer interactions that are needed to describe the dynamical behavior. We demonstrate that predictions need to be accompanied by uncertainty estimates for both model validation and hypothesis testing. We then introduce some of the techniques from the optimal experimental design literature to reduce the prediction uncertainty for dynamical variables of interest.

In Chapter 3 we analyze the convergence properties of some of the Markov Chain Monte Carlo (MCMC) algorithms that can be used to give more rigorous uncertainty estimates for both parameters and dynamical variables within a model. We lay out a straightforward procedure which gives approximate convergence rates as a function of the tunable parameters of the MCMC method. We show that the method gives good estimates of convergence rates for the one dimensional probability distributions we examine, and it suggests optimal choices for the tunable parameters. We discover that variants of the basic MCMC algorithms which claim to have accelerated convergence often completely fail to converge geometrically in the tails of the probability distribution.

In Chapter 4 we consider a different problem --- how to efficiently simulate stochastic dynamics within a biochemical network. We introduce a mixed dynamics simulation algorithm which describes the biochemical reactions where some of the species can be treated as continuous variables, but other species are naturally described as discrete stochastic variables. We then attempt to describe an approximation to the continuous dynamics in a situation where the discrete variables change on a much faster relative time scale, analogous to the quasi-equilibrium assumption made in fully deterministic systems. However our approximation method mostly fails to capture the true correction to the dynamics; we speculate as to the reasons for this.

title: Continuous-Time Tail Index Estimation
abstract: In applications to finance, insurance, physics and many other fields, statisticians are often faced with high quality datasets that exhibit deviations from the "normal behavior", caused by the extremes in the sample. As a consequence in recent years a great deal of research has been done in heavy-tailed modelling. Although much of the existing literature focuses on the discrete time case, the continuous-time heavy-tailed modelling is a very natural technique in many applications and therefore more attention should be paid to the continuous-time case. This is the motivation for the research in this dissertation. We will be focusing mainly on extending the Hill estimator (Hill (1975)) to estimating the tail index of continuous-time stationary stochastic processes. Since one can sample basically as many observations as possible from the continuous-time process, there is a temptation on the practitioner's part to use as large a sample as possible when applying the Hill estimator. We will show that this will lead in many instances to asymptotically inconsistent estimators.

title: PLANAR-FLOW MELT SPINNING: PROCESS STABILITY AND MICROSTRUCTURAL CONTROL
abstract: Various melt spinning embodiments have been developed over the past 30 years and have been widely used, particularly at bench-scale for the production of metallic glasses. Much of the processing science has been developed 'as-needed' by the metallurgical community. Commercial scale-up has been limited, primarily because of the difficulty in maintaining good product quality. As yet, pilot-scale, and larger, single stage melt-spinning machines have not become industrially significant. The broad aim of this work is to develop a scientific basis for some technological objectives.
One obvious processing restriction is the presence of surface defects on the product. A common span-wise defect, referred to as the cross-wave, is related to processing parameters. The key physics underlying the defect are found to be natural oscillations of the liquid metal puddle, akin to the oscillations of a plucked sphere of liquid. This discovery, not only provides a key piece of information about the defect and ways to eliminate it, but also ties this highly applied process to a classical fluid dynamics problem.
The planar-flow melt spinning process is known to become unstable for various combinations of control parameters. As with any manufacturing process, a wider range of control and outputs is desirable. In this spirit, a theory, based on capillarity constraining the liquid metal, is developed which predicts a range of stable operating conditions. This theory also suggests a technology to extend the range of stable operation. This technology has been developed and successfully reduced to practice. The theory is further developed to provide more intimate details of the flow structure and pressure drops in the process.
Another technologically driven element of this work is the examination of the cooling rates in the process and their manipulation using local heat transfer disruptions on the liquid metal puddle. This work demonstrates how product properties may be manipulated on a sub-millimeter scale.
Finally a detailed description of the experimental operating procedure and hardware is presented, in order that future researchers may not have to 're-invent the wheel' regarding many subtle aspects of the process.

title: AN EMPIRICAL ANALYSIS OF PENSIONS FOR THE LABOR MARKET
abstract: Empirical research of pensions and its role in the labor market has been limiting and has led to inconclusive and sometimes contradictory results. What is needed to have a better understanding of the role of pensions is better data that are longitudinal and national, include worker and firm information, and provide information that helps deal with endogeneity between certain variables. This dissertation discusses such a new data set and discusses the empirical uses of the data when investigating the role of pensions on firm productivity. This dissertation comprises of two chapters. Each chapter is discussed below.
Chapter 1, "Results from Integrating the Form 5500 Pension Information with the U.S. Census Business Register and the Longitudinal Employer-Household Dynamics State Data" discusses the process in creating a new, unique data set which is longitudinal and includes information about private firms, their employees, and the different pensions that they offer. This data has firm and pension information for all private employers in the United States for years 1994 through 2001 and added employee information for firms that exist in twelve states over the same period. This data set is shown to be far superior to any currently available data set.
Chapter 2, "Do Changes in Deferred Compensation Lead to Changes in Productivity?" empirically examines the effects on firm productivity when a firm terminates a defined benefit plan and replaces it with a defined contribution plan. The empirical analysis was done using the data set discussed in Chapter 1. The empirical results show that when performing two-step estimations and comparing one group of firms that kept their defined benefit plans to another group of firms that converted their pension plans, the group that converted experienced a reduction in productivity between the years 1995 and 2000. There is some evidence that this result occurred because workers no longer had the incentive to remain with the firm once the defined benefit plan was replaced, and as a result, workers were leaving the firm before gaining firm-specific skills. However, more work needs to be done to determine if the reduction in employee retention is truly the cause.

title: Know Your Insects
abstract: A graded project that can carry a young person through many years of work in entomology. The project material gives minimum instructions for beginning an entomology project. Included are an introduction to what an insect is, guidelines for making an insect collection including proper data collection and keys for the identification of specimens to order level, directions for making necessary collecting equipment, suggestions of how, when and where to collect, and lists references, and other aids that are available. The requirements for 3 years of general collecting for 4-H is included.

title: MILK COMPOSITION AND FARM BUSINESS CHARACTERISTICS: SUR ESTIMATION OF PRODUCTION FUNCTIONS VERSUS AN OUTPUT DISTANCE FUNCTION
abstract: The milk price received by New York dairy farmers is now primarily based on the amounts of the three main milk components: butterfat, protein, and other solids. Thus, by altering individual component production levels in respond to each component price, dairy farmers may increase their profits. It is, therefore, important for dairy farmers, first, to identify the production factors involved in milk production, and to examine their effects on each of the component production as well as aggregate milk.
For many years, economists and animal scientists examined the relationship between production factors and milk production, but one important aspect of milk production that has been overlooked is the effects of business factors on milk components. Although most business factors in milk production are not considered to be as crucial as factors like feed and breed type, the production performance of a dairy farm is in fact strongly connected to various business factors such as human capital, housing type, and milking frequency. Therefore, it is imperative that individual component production be examined as functions of production factors, including traditional inputs like feed, as well as business characteristics reflecting management. Only through this type of study will dairy farmers be able to comprehensively understand their production performance and fully realize their potential.
To accomplish this end, four single-output production functions using SUR and a stochastic output distance

function were estimated using the New York Dairy Farm Business Summary data from 105 farms in 2003 and 107 farms in 2004. Since only two years of data were available for this study, estimating production functions with panel characteristics were precluded. Thus, a year dummy variable was included to allow for the unobserved technical changes and environmental between the two years.

Based on the estimation results, this study examined (a) the effects of business factors and other inputs on aggregate milk and individual component production, (b) the technical efficiency of New York dairy farms that participated in the DFBS project, and (c) the relationships between the outputs. Consequently, twelve common factors were found to have significant effects on milk production among 22 total independent variables related to feed, breed, labor, capital, and other managerial and environmental factors. Of these 12 significant variables, the amount of commercial feed provided to a cow, quality of hired labor, capital intensity of a farm, productivity of land for home-grown forage, herd genetics, cow comfort level, BST use, and milking frequency, were shown to increase overall milk output as well as individual milk components. On the other hand, year dummy variable (2003=0 and 2004=1), average operator age, amount of home-grown forage provided to a cow, and percentages of Non-Holstein breeds on the farm were found to have negative effects on milk production.

From the stochastic output distance function, very little technical inefficiency was found in these participating New York dairy farms. The minimum value of estimated technical efficiency was 90% and the average was 96%. This implies that almost all of the participants in the DFBS project produce outputs at near the maximum possible output levels, given their production technology.

This study also examined the relationships between the outputs by computing the elasticity between outputs. The elasticity between milk and butterfat, and milk and protein were both found to be negative, while milk and other solids were found to be positive. However, these elasticities may not be particularly useful because dairy cows cannot be asked to alter their milk composition without changing inputs, and these output substitution elasticities are computed from a constant input vector.

title: THE ROLE OF ESTROGEN IN THE INDUCTION AND MODULATION OF SYSTEMIC LUPUS ERYTHROMATOSUS (SLE)
abstract: Ph.D. DissertationSystemic lupus erythematous (SLE) is a systemic autoimmune disease, characterized by circulating auto-antibodies to nuclear and cytoplasmic self antigens. A striking female predominance has been documented in SLE, with a female to male occurrence ratio of 9:1. Although the sex discrepancy in SLE has been attributed to sex hormones especially the female sex steroid estrogen, its importance is still controversial and other mechanisms are proposed, such as X inactivation, imprinting, differential exposures, etc. The present studies were undertaken to investigate the role of estrogen in inducing and accelerating lupus in lupus-prone and non-autoimmune mice and identify the possible mechanisms involved.

We first ovariectomized or castrated female or male lupus-prone SNF1 mice in order to determine the impact

that removal of physiological levels of sex hormones would have on the pathogenesis of lupus nephritis; exogenous 17?-estradiol (E-2) at a dose of 1mg/kg was also administrated to male mice. The results suggested that E-2 accelerated and exacerbated SNF1 lupus nephritis by inducing pathogenic idiotypic-reactive T cell populations that led to increased production of IdLNF1+ IgG which was deposited in the kidneys, resulting in nephritis. In, contrast, the removal of physiological level of testosterone had no effect. E-2 was also shown to induce the lupus phenotype and disease in the non-autoimmune mice, DBF1 mice. Further, the development of lupus nephritis in bone marrow chimeras derived from SNF1 mice of different genders or between SNF1 mice and the nonautoimmune-prone DBF1 cross, required either a female host and/or the addition of exogenous E-2.
The possible mechanism(s) underlying the effect of estrogen were also investigated. Thymectomy of SNF1 mice (at 30 days of age) delayed disease onset; however E-2 treatment induced disease in thymectomized mice, suggesting that the thymus was not required for E-2 induced upregulation of pathogenic idiotypic-reactive T cell populations. Lastly, our data suggest that estrogen?s effects on lupus nephritis were ER-? dependent; E-2 exposure led to decreased survival and nephritis in WT (ER?+/+) but not ER?-/-, and SNF1 immune cells constitutively expressed more ER? compared to DBF1, which was upregulated after E-2 exposure.Jerrie Gavalchin

title: Home Lawns Establishment and Maintenance
abstract: Every year Americans spend billions of dollars to make their lawns attractive. A turfgrass lawn increases property value, enhances the environment by filtering out atmospheric pollutants, reduces noise, and cools the area in the summer. A healthy lawn is more pest resistant, thus reducing the use of pesticides. The authors tell you how to analyze the site, have the soil tested, eliminate existing vegetation, drain and grade the land, add fertilizer or other amendments, select seed, prepare the seedbed, plant, irrigate, and mow. This edition explains integrated pest management and how its use can reduce reliance on pesticides. Illustrations are included.

title: Mapping the literature of emergency nursing.
abstract: Medical Library Association's Nursing and Allied Health Resources

Section's project to map the nursing literaturePURPOSE: Emergency nursing covers a broad spectrum of health care from trauma surgery support to preventive health care. The purpose of this study is to identify the core literature of emergency nursing and to determine which databases provide the most thorough indexing access to the literature cited in emergency nursing journals. This study is part of the Medical Library Association's Nursing and Allied Health Resources Section's project to map the nursing literature. METHODS: Four key emergency nursing journals were selected and subjected to citation analysis based on Bradford's Law of Scattering. RESULTS: A group of 12 journals made up 33.3% of the 7,119 citations, another 33.3% of the citations appeared in 92 journals, with the remaining 33.3% scattered across 822 journals. Three of the core 12 journals were emergency medicine titles, and 2 were emergency nursing titles from the selected source journals. Government publications constituted 7.5% of the literature cited. CONCLUSIONS: PubMed/MEDLINE provided the best overall indexing coverage for the journals, followed by CINAHL. However, CINAHL provided the most complete coverage for the source journals and the majority of the nursing and emergency medical technology publications and should be consulted by librarians and nurses seeking emergency nursing literature.Nursing and Allied Health Resources Section of the Medical Library Association

abstract: Previously Published by Basil Blackwell, Inc. 432 Park Avenue South, Suite 1503, New York, NY 10016. Copyright 2005 by Neil Hertz. All rights reserved.Neil Hertz's long-awaited volume of essays explores the notion of the sublime in literary and psychoanalytic texts from Longinus to Freud. The End of the Line

focuses on "authorial surrogates" -figures who appear in literature, philosophy, or psychoanalysis as emblems of activity of writing that has produced the work. George Eliot's Mr. Casaubon or a mangy dog in a novel by Flaubert emerge in Hertz's readings as doubles or scapegoats; through masterful analyses Hertz locates the pressures that produce these surrogates -pressures, he shows, that are crucial to the creation of great art. Hertz's work has long been famous for its extraordinary range as well as its uncompromising rigor. Although its subject is blockage, repression, and surrogates, The End of the Line is a brilliant and complete critical performance.

title: A DYNAMIC PARTICIPATION DECISION MODEL APPLIED TO THE CONSERVATION SECURITY PROGRAM FOR NORTHEASTERN UNITED STATES DAIRY FARMS
abstract: The Conservation Security Program was authorized in the 2002 Farm Bill and is hailed by many observers as the first true ?green payments? program for working lands in the United States. Previous analysis and anecdotal evidence for similar conservation programs show that premature termination of contracts is a persistent issue. This type of producer behavior is not easily explained using the standard assumptions of profit-maximization under perfect information and perfect rationality. Rather, this unexpected termination behavior demonstrates the need for analyses that take into account biophysical complexities and alternative decision-making assumptions. An alternative set of behavioral assumptions is explored in this research that employ descriptive rather than normative participation decision rules.
The objective of this research is to explore the impact of alternative behavioral assumptions and dynamic biophysical effects of conservation practices on the participation and termination decisions of New York dairy producers. A simulation model is constructed to represent the effects of selected biophysical processes on farm profitability, producers? ability to gather and utilize this information, and finally their decisions to participate in the program. The results of this simulation model provide insights concerning observed termination behavior and suggestions for policy design and implementation.
The results of the dynamic participation decision model indicate that premature termination of CSP contracts is possible and even probable under certain conditions. These conditions include the complex biophysical effects of conservation practices, behavioral characteristics of decision makers, and payment schedules of the Conservation Security Program. These are all significant factors affecting if and when producers decide to termination CSP contracts. Termination decisions, in this model, are a result of learning processes, that is, the producer?s realization of new information concerning the profitability, or net revenue from participating in the Conservation Security Program.
Behavioral characteristics play a significant role in shaping producers' learning processes and the formation of expectations of net revenue from the CSP contract. Most important for determining participation is the magnitude of the producer's initial estimation error as well as delays in updating their perceptions

and expectations of net revenue. These delays determine a producer's adjustment times for perceiving new information and the incorporation of that learning into new expectations about net revenue. This expectation formation process can further encourage farmers to terminate their CSP contracts by creating greater amounts of volatility in expectations. The type of decision rule used by the farmer is also of significance when determining if or when a farmer might terminate participation in CSP. This analysis examines ten alternative decision rules.

This analysis presents several implications for pragmatic policy solutions to the problem of premature termination of CSP contracts. Foremost, policy makers should look beyond typical cost/benefit models of decision-making when designing inventive structures for conservation programs. Taking into account alternative decision-making behavior, this research recommends an alternative payment schedule to what was implemented in the 2005 CSP sign-up. A more robust policy would be to vary the payment rates to compensate for the expected downturn in farmer perceptions and expectations. Evaluation of several dynamic payment schedules indicated that there are a variety of possible schedules that can increase initial sign-up rates, decrease termination rates, and decrease government expenditures simultaneously. The policy ?fix,? suggested by this analysis, is robust over variations in behavioral characteristics and for multiple decision rules. With this approach, it is possible to simultaneously decrease government expenditure and decrease cumulative termination rates.

title: Artificial Insemination to Cloning: Tracing 50 years of Research
abstract: Tremendous changes in reproductive biotechnologies of animals and humans have occurred during the past 50 years, more than occurred in the previous millenium. The book is prefaced with a short chapter emphasizing what qualities the author believes a person should cultivate in the pursuit of knowledge, and the love of sharing it with others. The following chapters describe advances in understanding reproductive physiology of cattle, horses, swine, sheep, goats, rabbits, dogs and ferrets through the research started by Professor Glenn Salisbury in 1939, and continued by others at Cornell University through 1998. Studies included research on sexual behavior in males and females, spermatogenesis and oogenesis, sperm and oocyte preservation, artificial insemination, embryo culture and cloning. Finally, and importantly is a reminder that all researchers have a great responsibility to combine high ethical, moral and research standards in the pursuit of truth. Abstracts of and references to 489 papers published from 1939 to 1998 are included. Compressed versions of the book with search indexes that can be downloaded and expanded on your personal computer are also provided.

title: Pre-electronic Age References on Reproductive Physiology Across Many Species of Mammals and Birds
abstract: As a graduate student in the late 1940s, Robert Foote wanted to expand his knowledge of comparative reproductive physiology, nutrition and genetics for professional improvement and to assist hundreds of undergraduate students that he helped teach. Soon, he had 60 scientific journals, plus abstract journals, that he checked every month. He developed triplicate abstract forms with a 3" x 5" perforated reference form to file by author with two 5" x 8" forms to add a brief abstract cross-filed under two subject matter headings. Included was a notation to indicate that a reprint had been sent for. By the time of the electronic age in the early 1980s, Robert Foote had accumulated about 15,000 reprints and 25,000 references. These included classic bulletins, a commonly used route to publish scientific data in the old days, as few scientific journals were available. The species and subject covered are summarized with typed references following. This typed list was started in 1966 to help about 200 undergraduates that Robert Foote taught.

title: A Workload Adaptive Voltage Scaling Multiple Clock Domain Architecture
abstract: This thesis presents a comprehensive system for allowing a Multiple Clock Domain (MCD) processor to adapt to its workload in an efficient manner. We present adaptive techniques at both the architecture and software levels. These techniques allow our system to either meet specified throughput demands while consuming as little energy as possible, or to stay within an average power budget while providing the highest possible throughput.

We first present an architecture-level adaptive system. This system adapts the voltage/frequency configuration of the MCD processor to meet the workload of a single application efficiently. As its input, this system can take either a throughput goal to meet using the least possible energy, or an average power level to remain below. We also show that our adaptive system can give an MCD processor increased tolerance to changes in performance and power dissipation due to variations.

Next, we extend this adaptivity to multiprogrammed workloads. We present a scheduling algorithm that considers the throughput goals of each running application. Using this feedback, it schedules the applications in such a way as to minimize total energy consumption without altering the throughput of the individual applications.

Finally, we present a system that allows individual applications to determine their throughput by comparing their actual progress to their desired progress rate. This system acts as a bridge between our architectural and inter-program adaptive systems. Each application's desired throughput is used in two ways. First, this throughput becomes the target throughput for our architecture-level system. Second, this throughput information provides the feedback that allows our scheduler to determine how it should schedule the application workload to minimize energy.

title: Imaging Single-Electron Charging in Nanostructures by Low-Temperature Scanning Force Microscopy
abstract: In this thesis we investigate Coulomb blockade phenomena and single-electron charging effects in two nanoscale structures: Long semiconducting carbon nanotubes (CNTs) and gold nanoparticles that are linked to a CNT by an organic molecule. While gold nanoparticles naturally exhibit single-electron charging at low temperature, it is disorder that causes the formation of quantum dots in long semiconducting CNTs at low carrier density. Our instrument of choice is a lowtemperature atomic force microscope (AFM) that is sensitive to electrostatic sample forces. A theory of the interactions between single-electron charging of

a quantum dot and the AFM tip and cantilever is worked out in linear response. In semiconducting CNTs we resolve single-electron charging events in the resonance frequency of the AFM cantilever. The AFM?s spatial resolution allows us to locate the quantum dots and address them individually. We extract the size of the quantum dots, their gate couplings, and exemplify how to extract their charging energy from the AFM measurements. We frequently observe interaction between neighboring quantum dots and characterize their interdot coupling. The evolution of the quantum dots in CNTs with gate voltage reflects the underlying potential energy landscape for the carriers on the tube. We observe the CNT band structure and extract quantitative information about the disorder potential. On the gold nanoparticle sample, we combine dissipation and frequency shift measurements by our AFM. In addition to the electrostatic gate couplings and the charging energy, this combination allows us to characterize the tunnel coupling between the gold nanoparticle and the CNT, which is acting as a lead.

The power of the demonstrated force probe techniques lies largely in the local nature of the measurement. Sensitive, spatially resolved information on electron transport is available even in the absence of device conduction. This advantage is apparent in the single-contact geometry of the gold nanoparticles, but also demonstrated on CNTs.

title: Interactions Between North African Vegetation and the African Easterly Jet: A Mechanism for Abrupt Climate Change
abstract: Committee members: Dr. Kerry Cook, Dr. Stephen Colucci, and Dr. Bryan IsacksModeling studies and paleoclimate evidence of the mid-Holocene, 6,000 years ago, indicate that the potential for rapid climate change exists over northern Africa. A regional climate model that produces an excellent representation of today's climate over northern Africa is used to simulate the summer climate under present day solar forcing and SSTs and several prescribed static idealized zonal vegetation distributions. The purpose is to isolate and understand the role of interactions between vegetation and the dynamics of the West African summer monsoon in generating rapid climate change. Simulations with prescribed and interactive vegetation distributions are analyzed.

In simulations with prescribed idealized vegetation, the regional model simulates only small differences in precipitation when the southern desert border is located between 10.0N and 17.9N. However, when the desert border is moved only 180 km, from 17.9N to 19.4N, summer precipitation increases by a factor of 5 over the Sahara, and the zonal structure observed in the present day climate is eliminated. These precipitation anomalies are associated with a 50% reduction in the magnitude of the African easterly jet, a 20% increase in the magnitude of the low-level westerly jet and a deepening and moistening of the thermal low. The model suggests that when the southern desert border is located north of a threshold latitude, the positive soil moisture anomalies beneath the region of maximum vertical velocity associated with the thermal low support positive low-level moist static energy anomalies, which are indicative of strengthened convection.

Asynchronous coupling with a simple vegetation model reveals that when the initial desert border is located at 20.9N, a new equilibrium vegetation distribution results in which the central Sahara is vegetated, indicating that the interactions between vegetation and the atmosphere may produce rapid climate change. When the initial desert border is located at 10.0N, the equilibrium vegetation distribution closely resembles that of the present day, suggesting that the atmospheric conditions may allow regrowth of vegetation in a deforestation scenario under present day solar and SST forcings.This research was funded by the NSF Award ATM - 0415481 and the Cornell University Graduate Student Fellowship.

title: Audio-Visual Archiving: Comparing Memory Institutions and Commercial Industries
abstract: This presentation will compare and contrast the audio-visual reformatting carried out in memory institutions with the production, distribution, and archiving of born digital content by record labels, television broadcasters, and motion picture producers. For sound recordings, digital practices have been established in both memory institutions and the industry, although issues regarding multi-track productions are troublesome for the industry. For video, digital approaches are widely used for reformatting by libraries and for new broadcast production, but most video masters continue to be recorded on conventional digital videotape rather than as media-independent digital file formats. For theatrical films, most memory institutions continue to reformat using proven photo-chemical approaches. Meanwhile, the production of new theatrical films is genuinely hybrid: Hollywood's current workflow mixes digital and film-based stages and elements. It is also the case, however, that high costs and the lack of relevant standards prevent motion picture producers from identifying and implementing a clear-cut digital solution for the long-term archiving of their valuable production assets. In all three areas--sound, video, and cinema--memory institutions and the industry face similar problems. Will they find ways to share their investigations and develop common solutions?

title: Audit and Certification of Digital Repositories: Exposing Risk and Fostering Collaboration
abstract: Over the last three years, the RLG - NARA Task for on Digital Repository certification has worked to develop a checklist which would allow objective evaluation of digital repositories and archives. The checklist was based upon international standards and community best practices for digital preservation as well as influences from information technology and information security standards. The goal was to develop metrics to evaluate three aspects influencing repository trustworthiness: the characteristics of the archiving organization that affect performance, accountability, and business continuity; technologies and technical infrastructure employed by the repository; and finally the processes and procedures utilized by the repository. A draft checklist was released for public consumption and comment in August 2005, leading to further development. In addition, the checklist has been leveraged by the Center for Research Libraries Auditing and Certification of Digital Archives project and used in test audits of three digital repositories and archives. Through public comment, practical application, and other CRL project activities, we have made further progress toward the development of a fully-fledged program of audit & certification for digital repositories. This presentation will discuss checklist development, envisioned uses of the checklist, the emerging audit & certification process, potential audit & certification process outputs, and compliance issues.

title: The nestor Catalogue of Criteria for Trusted Digital Repository Evaluation and Certification
abstract: The Criteria for Trusted Digital Long-Term Preservation Repositories (urn: nbn:de:0008-2006060710 or http://edoc.hu-berlin.de/series/nestor-materialien/2006-8/PDF/8.pdf) have been developed by the nestor project and are now open for public comment. This criteria catalogue primarily addresses cultural heritage organizations, federal archives, libraries and museums and is designed as a guideline for the planning and setup of a digital long-term preservation repository. Secondarily, this catalogue can be an orientation guide

for software developers, third party vendors or service provides from the private sector. The nestor catalugue focuses on its applicability in Germany . Still, it must be discussed internationally and should adhere to international standards.

title: Preservation Pressure Points: Evaluating Diverse Evidence for Risk Management
abstract: Preservation Pressure Points: Evaluating Diverse Evidence for Risk Management -- Establishing a comprehensive understanding of the effectiveness and trustworthiness of a digital repository requires a broad range of evidence. Preservation can be considered as a complex spatial and chronological network of challenges, and associated risks. For example the organisational, financial, technological and operational contexts within which a repository resides and the extent to which it is capable of managing them must be ascertained if an audit is to be able to assert the likelihood of the institution's success. Significant effort must be directed towards the definition of methodologies for identifying appropriate classes of evidence, to their evaluation, and to the attaching of weight to them. Formal means are required to facilitate the analysis and comparison of disparate evidence types in order to enable auditors to accommodate a diverse range of physical, testimonial and experiment-based proof. In addition to binary systems of inquiry (e.g., does the organisation have a mission statement?) auditors must display an ability to distinguish the most persuasive examples from those that provide less substantive evidence of organisational competence. Similarly, if, for instance, a significant proportion of staff reveal that they have no idea of the content of their organisation's mission statement then this must be reflected in the overall organisational assessment. A comprehensive insight, and consequent decision, can only be reached after fully exploring the evidential basis upon which compliance is to be founded. This discussion of evidential appraisal techniques for repository audit reflects the series of pilot audits undertaken by the Digital Curation Centre within a selection of UK data centres and archives, including the Beazley Archive and the British Atmospheric Data Centre.

title: Repository Institutionalization: What makes it worth becoming infrastructure?
abstract: Repository Institutionalization: What makes it worth becoming infrastructure? Since the advent of inexpensive or open-source institutional repository software, libraries and other institutions have attempted to wrestle with delivering services that could justify supporting the repository through chargebacks of some kind; yet a major problem has been persuading people to fill the repositories with content of adequate value to prospective user communities. Since 2003 we have been running DSpace repository software in the School of Information, University of Texas at Austin, at first simply as a testbed for student work but since spring of 2005 as an institutional archival repository. In the course of this experience, following the ?seed-evolve-reseed? model developed by Gerhard Fischer at the University of Colorado for collaborative development of computing environments, we have begun to demonstrate the value of such a repository in several different directions: fulfilling the state of Texas statutory requirements for preserving official documents (in which the official version of administrative information is posted on the School?s website); providing faculty (and students) with preprint and postprint exposure of their work; providing secure storage for learning objects, including presentations and tutorials; providing secure archiving for digital materials of historical value both to the School and to the discipline; providing an environment for students to work on the problems of digital archiving, populated with objects that will over time and in their turn demonstrate further problems of digital

archiving; and providing the Information Technology service with a secure archive for versions of installed software and content. These uses within the School alone are beginning to weigh securely enough in the balance to warrant commitment of funding for the provision of infrastructure to the tasks of administering and delivering educational services.

title: DAITSS and the Florida Digital Archive
abstract: The Florida Digital Archive (FDA) is a digital preservation repository run by the Florida Center for Library Automation (FCLA) for the use of the eleven public universities of Florida. The FDA went into production in November 2005. It ingested 108,607 files (2.2 TB) in the first 6 months of operation. The FDA uses a locally developed software application called DAITSS to support the repository functions of ingest, data management and dissemination, and the preservation functions of format normalization and format migration. Functionally, DAITSS consists of a set of services. The Ingest Service performs format validation, extraction of technical metadata, creation of derivative files through normalization and/or migration, and storage preparation. Storage Maintenance assures that stored masters remain good copies on readable media. The Access Service is responsible for access control, reporting, and building Dissemination Information Packages in response to requests. Other services include Withdrawal and Repository Management. The system does not support discovery functions for end-users or real-time online access to archived materials. It can, however, be used as a preservation back-end to institutional repositories, publishing systems, digital libraries, or other user oriented applications. Following the OAIS reference model, DAITSS assumes a community of Producers who select, prepare and submit materials for preservation. In the FDA context, these are the libraries of the public universities of Florida, which have negotiated archiving agreements with the repository. To date, most submissions have been preservation masters from local digitization projects, and electronic theses and dissertations (ETDs). This presentation will give an overview of the Florida Digital Archive and the underlying DAITSS application, which is targeted for release as Open Source Software in 2006.

title: Fedora: Complex Objects, Information Networks, and the Challenges of Digital Preservation
abstract: Fedora: Complex Objects, Information Networks, and the Challenges of Digital Preservation -- We are at a point where the scope, definition, and uses of digital libraries and institutional repositories are changing along with the process of creating and disseminating scholarly and scientific information. It is not enough to just store documents, datasets, images, and other resources in repositories where they can be searched and accessed. The networked landscape in which we live inspires more and calls upon us to develop information architectures that promote (1) the creation of complex digital objects that consist of both local and remote content, (2) the ability to interconnect digital objects that reside in distributed repositories, (3) the ability to re-use objects or their components in the creation of new resources. All of these requirements have implications for how we build digital libraries, repositories, and scholarly information systems in the future, and they also present significant challenges for digital preservation. In this talk I will discuss how the Fedora Project is approaching the digital preservation problem. In particular, I will highlight key aspects of the Fedora repository system and service framework that are preservation-enabling. I will also review current work undertaken by the Fedora Project in collaboration with the Fedora Preservation Working Group. This work entails the use of message-oriented middleware to facilitate alerting of preservation-noteworthy events

and the development of services to respond to such events.

title: DANS: Data Archiving and Networked Services
abstract: DANS is the new Dutch organization, which has been tasked with the preservation and permanent access to research data in the humanities and the social sciences. The two main scientific administrative organizations in the Netherlands, the Royal Netherlands Academy of Arts and Sciences (KNAW) and the Netherlands Organisation for Scientific Research (NWO), are jointly responsible for DANS. DANS aims to promote (interdisciplinary) collaboration with and among researchers. DANS is also the Dutch national partner in European and other international data organizations. DANS is also an intermediary to researchers for the delivery of large databases from organizations such as Statistics Netherlands, The Social and Cultural Planning agency and the Topographical Service. Already existing data archives like the social science data archive 'Steinmetzarchief' and the Netherlands Historical Data Archive (NHDA) have been merged in DANS. DANS has been mandated to expand and improve the current data research infrastructure. New initiatives for data services and data archives are being developed in fields where such facilities have been lacking until recently. These TOPical Programmes (TOPs) are set up in collaboration with research groups. Work on the renewal of the infrastructure for digital data archiving is in progress. Innovation and staying ahead in the ICT-development is one of the main spearheads of this new organization. To be able to apply fundamental research findings to systems used for archiving and providing access to data DANS has established its own development team. For the acquisition of data sets, collaboration with faculties, research schools and academic institutes will be invigorated. DANS developed in collaboration with researchers in the field and the Netherlands Ministry of Housing, Spatial Planning and the Environment (VROM) a user-friendly repository for research archiving. Now researchers are able to place their research data in DANS compliant data repositories. They can rely on a safe preservation and curation of their data an they can share their data with other researchers. DANS aims to make access to research data as open as possible.

title: The Norwegian Digital Radio Archive - 8 years later, what happened?
abstract: The Norwegian Digital Radio Archive -- The Norwegian Broadcast Corporation (NRK, www.nrk.no) and the National Library of Norway has for six years been working together to digitise the historical radio archive of NRK. The project aims at preservation, professional re-use, and general access. More than 50.000 hrs (170.000 programs) have now been digitised in high quality. The archive is built within the National Library of Norway, but serves as the every-day radio archive for NRK with their headquarters 1000 kms away. The archive is also now the repository where the National Library of Norway stores copies of the daily radio broadcast in Norway, enabling the archive to be updated on a daily basis. The archive is also integrated with FEIDE (www.feide.no), a federated authentication regime for the research and education sector in Norway. Based on the use of FEIDE, the National Library of Norway has established a role-based access control for the archive.

title: Co-operative Development of a Long-term Digital Information Archive
abstract: Data for the future - the kopal project -- The German project kopal develops a cooperative used long-term digital archive. The archival system of kopal could be used by different clients, just like a bank account. It is hosted by an experienced service provider and based on software by IBM. Its interfaces are open defined in a way, that it is possible to use open software and standard object formats to connect to them. As a result of the project an open archiving and exchange format for digital objects was specified, called Universal Object format. There is also an open source software library called koLibRI to build up objects, generate technical metadata and manage the communication with the OAIS-compliant system. Migration and emulation will be supported, but especially migration is an essential part of koLibRI and the concept of technical metadata within the data management. The archival system is ready to be used by the project partners and ca. 10 TB of data will be ingested until the end of the year 2006.

title: MetaArchive NDIIPP Partnership
abstract: The MetaArchive of Southern Digital Culture will discuss the first two years of deliverables (2004-2006) for their three year partnership for establishing a collaborative digital preservation network for southern cultural heritage materials. The MetaArchive of Southern Culture is a multi-institutional partner with the Library of Congress in their National Digital Information Infrastructure and Preservation Program (NDIIPP) and has established a distributed model for digital preservation. Headed by Emory University, this test-bed implementation network involves six different academic research libraries (Auburn University, Emory University, Georgia Institute of Technology, Florida State University, Virginia Polytechnic Institute and State University, University of Louisville) as well as a strategic alliance with the Stanford University based LOCKSS Program and the Library of Congress.
During the first two years of this project the MetaArchive partnership has implemented a collaborative digital preservation network, has tested the LOCKSS toolset for scale (3 terabytes), for ingest (HTTP and OAI-PMH), and for reliability (total system failure). The group has also developed a collection-level conspectus that inter-operates with LOCKSS ingest plug-ins and collection selection policies of the group. Included in this presentation will be a discussion of the collaborative partnership agreements and the forthcoming work on the next phases of the project which include establishing a non-profit entity that specializes in digital preservation networks for cultural heritage institutions, creating a formalized business model to advance our collaborative paradigm outside of our Library of Congress partnership, to conduct document format tests involving LOCKSS on-access migration and batch migration strategies, and to implement a preservation management framework that incorporates other open-source preservation software tools capable of integrating with our current LOCKSS-based network.

title: Digital Archive Partnership
abstract: For almost two years, the National Library of New Zealand (NLNZ),
Endeavor Information Systems and Sun Microsystems have been working together to design and implement a comprehensive digital preservation platform for New Zealand's National Digital Heritage Archive. NLNZ has developed the requirements for the platform and with Endeavor is completing the specifications. From

that, Endeavor is building a components-based application platform (called Kronos) and Sun is developing the overall reference architecture. A goal for all three organizations is to create a solution that is generic and applicable for any library with large and varied types of digital content. An independent peer review group has periodically met with the three organizations to ensure that the Kronos design is widely applicable to other libraries and complies with international standards. Our presentation describes why the partnerships formed and how they have evolved. The concept of the Peer Review Group will be examined as a method of ensuring industry-wide compliance and as a mechanism for explicating and resolving tension between partners.

title: Preservation of Federal Digital Publications
abstract: The U.S. Government Printing Office (GPO) is committed to ensuring permanent public access and preservation of U.S. Federal publications. Historically, preservation of the tangible materials has been handled in collaboration with the individual libraries participating in the Federal Depository Library Program. Advances in information dissemination and the need to preserve digital content has necessitated changes in processes associated with GPO's production and distribution of Federal publications. Working with U.S. Government agencies, depository libraries and other interested parties, GPO is moving to implement a life-cycle approach to publishing of Federal publications to ensure not only access, but preservation of the objects for the future. This presentation will focus on GPO's collaboration with other communities of practice and the development of FDsys, GPO's digital content management system.

title: Portico: An Electronic Archiving Service
abstract: The work of the academy ? research and teaching ? is not possible without reliable access to the accumulated scholarship of the past. One component of this scholarly record, academic journals, is increasingly electronic ? and fragile ? and its future accessibility is a growing concern. The recent statement "Urgent Action Needed to Preserve Scholarly Electronic Journals" endorsed by leading libraries and organizations such as ARL, ALCTS and others underscores the urgency of this community need. But the scale and complexity of the technology infrastructure, specialized expertise and quality control processes necessary to preserve electronic resources exceeds that which can be supported by any individual library or institutional budget. This presentation will provide a brief history of Portico, the not-for-profit electronic archiving service developed in response to the library community's need for a robust, reliable means to preserve electronic scholarly journals. Portico was initiated by JSTOR and has been developed with the initial support of Ithaka, The Andrew W. Mellon Foundation, and the Library of Congress. Portico's mission is to preserve scholarly literature published in electronic form and to ensure that these materials remain accessible to future scholars, researchers, and students. In addition to an overview of the Portico service and access model developed with input from publishers and libraries, the presentation will include an update on library and publisher participation and the status of Portico's archival operations.

title: The International e-Depot: e-Journal Archiving at the National Library of the Netherlands
abstract: Electronic journals dominate the field of academic literature, and it is of great importance to the international scientific community that this electronic intellectual output remains accessible in perpetuity. It is uncertain, however, whether the traditional model, based on national deposits and geographical frontiers, will be able to guarantee the long-term safety of the international academic output in a digital form. Academic literature is produced by multinational publishers, and has often no longer a country of origin that can be easily identified and thus no obvious guardian. Hence, in the traditional model there is a huge risk of academic records being lost forever. A systematic and more concentrated approach is needed to address this unacceptable risk. In this presentation we discuss the policy and ambitions of the National Library of the Netherlands (Koninklijke Bibliotheek, KB) regarding digital archiving of electronic publications. We discuss three possible threats against permanent access, and we propose a coordinated and systematic approach to address these risks: the Safe Places Network. This paper also includes a comprehensive overview of the e-Depot system and the KB approaches to digital preservation.

title: LOCKSS: Lots of Copies Keep Stuff Safe
abstract: People with responsibility for scholarly assets agree that digital preservation is important. Tomorrow's readers will need today's materials; without preservation they won't exist. Librarians and publishers are asking two fundamental questions: From this moment on, who will have custody of society's electronic information? From this moment on, who will control and govern society's electronic archival assets? With LOCKSS over 150 libraries and over 80 publishers are working together to ensure no one organization has control over our intellectual heritage. By ensuring libraries can build collections and retain their role as long-term memory organizations in the electronic environment LOCKSS avoids the social hazards of centrally controlled information. With CLOCKSS 12 large publishers and seven libraries are working towards similar goals. For over 8 years the OAIS-compliant, format-agnostic, open source LOCKSS system has been demonstrating it can ingest a wide range of web content, audit and repair it to ward off damage and attacks, and transparently deliver it to readers with transparent on-access format migration. [www.lockss.org]

title: Bringing Many Tools Together: Building a System of Co-operating OAIS's in the MathArc Project
abstract: Bringing many tools together to build a system of co-operating OAIS's in
the MathArc project. The MathArc project has created a protocol, software, and registry that enable multiple institutions to share and store digital objects in each other's OAIS repositories, regardless of the nature of each system's underlying repository. In the pilot version, the Goettingen State and University Library (SUB) and the Cornell University Library (CUL) are sharing, storing, and managing collections preserved in Goettingen's kopal system (based on DIAS) and Cornell's CUL-OAIS (based on aDORe). The tools and standards used to build the system are familiar to those working in the digital preservation field and have been described and presented in many places. They include METS, OAI-PMH, PREMIS, JHOVE, LOCKSS, aDORe, and the kopal version of DIAS. This presentation describes not how they work individually, but how they all work together in the MathArc system.

title: The Entity (N2T) Resolver: low-risk, low-cost persistent identification
abstract: Low-Risk Persistent Identification: the "Entity" (N2T) Resolver -- The N2T ("entity") identifier resolver addresses the same problem as URN, Handle, and DOI resolvers, but does so without complex or proprietary software components. N2T is lower-risk than those resolvers because it relies only on off-the-shelf open-source components, and it is the only resolver to acknowledge and address the "namespace splitting problem". N2T (Name-to-Thing) is both a persistent identifier resolver and a consortium of cultural memory organizations. The consortium has no fees or requirements, and merely offers its members the option to publicize a protected form of their URLs supported by the resolver. The resolver is a small, standard web server run in several mirrored instances by consortium volunteers under one hostname rented for about $30 USD per year. The resolver works equally well with any identifier scheme (URLs, ARKs, Handles, DOIs, URNs, PURLs) that can be expressed inside a URL.

title: Global Digital Format Registry (GDFR): An Interim Status Report
abstract: The format of a digital object must be known in order to interpret the information content of that object properly. Strong format typing is therefore fundamental to the effective use, interchange, and preservation of all digitally-encoded content. In terms of the OAIS reference model, format typing is a component of an object's representation information. Formats themselves also have representation information--primarily, the set of syntactic and semantic rules for encoding content into digital form--that must be preserved to address the concern raised by the Library of Congress's recent planning report, Preserving Our Digital Heritage: "Longevity of digital data and the ability to read those data in the future depend upon standards for encoding and describing, but standards change over time." The Andrew W. Mellon Foundation has funded an effort by the Harvard University Library to create a Global Digital Format Registry (GDFR) that will provide preservation practitioners with sustainable services to store, discover, and deliver representation information about digital formats. This presentation will provide an update on GDFR project activities.

title: nestor II: e-Science and Preservation--A Perfect Match?
abstract: e-Science and Preservation - A Perfect Match: The hard sciences have worked for many years towards global collaboration on an infrastructural and workflow level. The concepts and technologies eveloped in this venture are increasingly being adopted by other disciplines including the social sciences or the arts and humanities. In Europe these disciplines aim to establish an integrated e-Science landscape to benefit from the existing resources and experiences attained by the "hard sciences". Current humanities projects under the e-Science umbrella are on a promising route. The preservation community could benefit greatly from the e-science community in the strive for - amongst other - sharing storage resources while maintaining local autonomy; interoperability and resource integration on a semantic level; adaptability for long-term stability; sharing services and synchronising workflows. As part of its mission as a national coalition for digital preservation, Nestor II aims to network the e-Science and preservation communities and further the

transfer of concepts and tools between them.

title: Digital Data Preservation and Curation: A Collaboration Among Libraries, Publishers, and the Virtual Observatory
abstract: Digital Data Preservation and Curation: A Collaboration Among Libraries,
Publishers, and the Virtual Observatory. Astronomers are producing and analyzing data at ever more prodigious rates. NASA's Great Observatories, ground-based national observatories, and major survey projects have archive and data distribution systems in place to manage their standard data products, and these are now interlinked through the protocols and metadata standards agreed upon in the Virtual Observatory. However, the digital data associated with peer-reviewed publications is only rarely archived. Most often, astronomers publish graphical representations of their data but not the data themselves. Other astronomers cannot readily inspect the data to either confirm the interpretation presented in a paper or extend the analysis. Highly processed data sets reside on departmental servers and the personal computers of astronomers, and may or may not be available a few years hence. We are investigating ways to preserve and curate the digital data associated with peer-reviewed journals in astronomy. The technology and standards of the VO provide one component of the necessary technology. A variety of underlying systems can be used to physically host a data repository, and indeed this repository need not be centralized. The repository, however, must be managed and data must be documented through high quality, curated metadata. Multiple access portals must be available: the original journal, the host data center, the Virtual Observatory, or any number of topically-oriented data services utilizing VO-standard access mechanisms.

title: Preserving Things that Count: Exploring partnerships among domain specific repositories, institutional repositories, and social science researchers
abstract: In developing and debating digital repositories, the digital library world has devoted more attention to their missions and roles in supporting access to and stewardship of academic research output than to discussing discipline, or domain, specific digital repositories. This is especially interesting, given that in social science these domain-specific repositories have been in existence for many decades. The goal of this presentation is to juxtapose these two kinds of repositories and to suggest ways that they can help build partnerships between themselves and with the research community. It is based on the fundamental idea that all the parties involved share important goals, and that by working together these goals can be advanced successfully. We will begin by characterizing the life cycle of social science research, before turning to key elements of the two different kinds of repositories, and then to our recommendation that researchers and the two different kinds of repositories can forge partnerships. The key message is that by visualizing the role of repositories explicitly in the life cycle of the social science research enterprise, the ways that the partnerships work will be clear. These workings can be seen as a sequence of reciprocal information flows between parties to the process, triggers that signal that one party or another has a task to perform, and hand-offs of information from one party to another that take place at crucial moments. This approach envisions both cooperation and specialization. The researcher produces the scientific product, both data and publications; the institutional repository has specialized knowledge of campus conditions and the opportunity to interact

frequently with the researcher; and the domain-specific repository has specialized knowledge of approaches to data in a specific scientific field, for example domain-specific metadata standards, as well as the ability to give high-impact exposure to research products.

title: Virtualisation of Simple Scientific Data Objects
abstract: Virtualisation of Simple Scientific Data Objects.Capturing OAIS defined representation information in a standardised way is critical for the preservation and future reuse of scientific data. The structure of a scientific data object needs to be defined so that a future user can map the data bits to the actual scientific data. The semantics associated with the scientific data also needs to be defined so that the data can be understood and used by a user from the appropriate designated community. This presentation will show how simple scientific digital objects (tables, images etc.) can be described and "virtualised" by using representation information in the form of EAST file format descriptions (structure) and the corresponding DEDSL data dictionaries (semantics). It will also be shown that in some real life cases the EAST and DEDSL standards need to be extended so that they can fully describe the simple objects. Tools and APIs will be demonstrated

that take the structure and semantic definitions for a simple scientific digital object and automatically read the data it contains and render it in the appropriate way.

title: Web Archive Switzerland
abstract: Web Archive Switzerland is a pilot project undertaken in collaboration with the Swiss Cantonal libraries as part of the e-Helvetica Project at the Swiss National Library (SNL). The mission of the SNL and the Swiss Cantonal libraries is to collect and archive all Swiss publications, both printed and electronic. The objective of the e-Helvetica Project is to fulfill this mission for electronic publications. The Web Archive Switzerland pilot project recently designed and tested a shared workflow for selecting, collecting, cataloguing, archiving and disseminating non-commercial Swiss web resources. Within the workflow the Cantonal libraries are responsible for the identification, selection and announcement of data on the Web. The SNL is responsible for the web-harvesting (objects and rights), cataloguing, archiving and dissemination of those identified web resources. The aim of this co-operation is to share resources and knowledge. This presentation will give some historical context to Web Archive Switzerland and discuss the collaboration with the Cantonal libraries and the shared workflow. The approach chosen for selecting, cataloguing and harvesting the web resources will be highlighted as well as our experiences to date. The presentation will conclude with some ideas on how we are planning to disseminate the web resources. For further information on the e-Helvetica Project (in German and French), see: <http://www.e-helvetica.ch>.

title: Intrinsic and Extrinsic Contributions to the Development of the Zebrafish Olfactory Epithelium
abstract: Kathleen Whitlock, Ph.D.- advisor, Kenneth Kemphues, Ph.D.- committee member, David Lin, Ph.D- committee memberI have used the zebrafish, Danio rerio to study the following stages of olfactory sensory system development: the cell movements underlying olfactory placode (OP) formation, environmentally induced gene expression changes in the differentiating OP and modulation of gene expression changes in sensory neuron development.

Cranial neural crest (CNC) and placodes both contribute to vertebrate sensory structures. Little is understood about the extent of cellular mixing between the CNC and OP fields during OP formation. I used live imaging and molecular markers in fixed tissue to follow the CNC and OP fields during OP formation. I found that while the CNC cells associate with and eventually surround the OP, little cell mixing occurs between the fields during this process.

The OP develops into the olfactory epithelium (OE). I explored the effects of the nenvironment on gene expression in the developing OE. My lab previously showed that zebrafish form and retain olfactory memories of the odorant phenylethyl alcohol (PEA). I performed microarray analysis using the OEs of PEA imprinted fish to identify upregulated genes. One of the genes I identified was the transcription factor otx2. Otx2 is expressed in the developing and adult OE. The number of otx2 expressing cells is significantly increased in juvenile and adult OE of PEA exposed fish. I showed that otx2 cells also express neuronal markers suggesting that PEA exposure leads to an expansion of a neuronal precursor population that is maintained throughout life.

The environmentally induced gene expression changes I observed could be a consequence of activating the immediate early genes (IEGs), which are transcription factors that are rapidly upregulated in response to

sensory stimuli. To test if IEG expression was affected by odorant exposure my lab and I exposed juvenile zebrafish to a number of odorants and examined the expression of three IEGs in the developing OE. We found a significant change in the expression of the IEG, c-fos when fish were exposed to odorants of behavioral relevance. My studies provide a better understanding of how the OP forms and how the environment affects the differentiation of cells within the OE.Field of Genetics and Development NIH Training Grant (GM07617), GAANN (Graduate Assistants in Areas of National Need) Fellowship P200A000118, Cornell Center for Vertebrate Genomics Graduate Research Fellowship, NIH Grant R01 DC04218 (awarded K. title: Digital Preservation in the UK
abstract: The UK scene -- David Thomas will focus on the Seamless Flow programme being undertaken at the National Archives of the UK. This is an ambitious plan to develop a fully comprehensive digital preservation service for the UK central government. It covers the selection of record for permanent preservation, their transfer to the National Archives and their storage, preservation and delivery to users. Crucially, the programme is doing work in two other spaces ? the intermediate storage of digital material which has a long-term business value to government (such as files relating to radioactive waste) and resource discovery. Many of the hard lessons learned on this challenging programme have a wider application and he will be sharing these with you.

title: A Dynamic Solution for Electronic Records: The National Archives and Records Administration's Electronic Records Archives
abstract: After a year long design competition, in September 2005 the National Archives and Records Administration awarded to Lockheed Martin Corporation a contract valued at $308 million to develop and operate the Electronic Records Archives (ERA) system. The system will enable a comprehensive transition of NARA?s governmentwide management of the records of the U.S. Government into the realm of e-government. It will automate records management processes, such as scheduling and appraisal, transfer of records to NARA, and destruction of temporary records. These functions will be applicable to records of all types, and support NARA?s different lines of business in the National Archives, Presidential Libraries, and Federal Records Centers. The system will also enable NARA to realize its vision of preserving and providing continuing access to any type of electronic record, free from dependence on the hardware and software originally used to create and store it, for as long as the records need to be retain, which includes for the life of the republic. The speaker will describe the architecture and processes for digital preservation and access in the ERA system.

title: CADSL: China Archives of Digital Scientific Literature Initiatives
abstract: Dr. Zhang will present the China Archives of Digital Scientific Literature (CADSL) Initiative, proposed to the Ministry of Science and Technology of China, as the result of a feasibility study by the

National Science and Technology Library of China. Based on a need and crisis analysis, a distributed network of trusted archives with sustainable planning and administration mechanisms is suggested to preserve digital scientific information resources, including foreign published literature, home-grown literature, and scientific web resources. Outlined in the proposed initiative is (1) a distributed and shared system of responsibility to archive the targeted resources, (2) a framework of guidelines for intellectual property protection of preserved materials, (3) an open and continuous certification process for trusted repositories, (4) a rigorous set of outlines of technological, workflow management, service level agreement requirements for prospective archives, and (5) a public and yet competitive funding mechanism to utilize multiple resources for the initiative. Ways to mobilize research and educational institutions into the initiatives and future efforts to promote and collaborate with scientific data preservation and cultural heritage preservation are discussed in the end.

title: CARBON IN RIPARIAN SUBSURFACE ECOSYSTEMS: SOURCES, LABILITY, AND SPATIAL PATTERNS
abstract: Numerous studies suggest that denitrification in riparian zones removes nitrogen from groundwater

as it moves from terrestrial to aquatic ecosystems. However, removal rates vary widely among sites complicating the incorporation of riparian zones into models of nitrogen movement across landscapes. Because denitrification in the riparian subsurface is often limited by the supply of microbially-available carbon, explaining how and why carbon supply varies among riparian zones using mappable landscape attributes holds practical and theoretical appeal. First principles suggest three carbon sources for subsurface microbes: (1) dissolved organic carbon leached from surface soils; (2) deep plant roots; and (3) buried, carbon-rich soil horizons deposited long ago. Working in Rhode Island USA at riparian zones mapped as outwash and alluvium, I investigated the relative importance of different carbon sources to 3 meters depth.

Field and laboratory experiments showed that both roots and buried horizons can supply carbon in the shallow subsurface (40-75 cm), but that buried horizons dominate below 75 cm. Radiocarbon dates and results from ingrowth cores showed that roots 40-75 centimeters deep grow and decompose on decadal time scales and form patches of organic matter that may influence nitrogen removal from groundwater. However, in both alluvial and outwash profiles, most roots below 80 cm are relics (usually > 140 years old) and therefore do not act as direct carbon conduits between the surface and deep subsurface. Laboratory incubations of buried soils from many sites demonstrated that high rates of carbon mineralization associated with these soils are common. In-situ groundwater incubations and 14C dating demonstrated that metabolism of ancient carbon constitutes at least 31% of total carbon mineralization >2 meters below the surface at some sites.

My results suggest that: (1) the depth of the biologically active zone extends as deep as buried horizons; (2) on outwash and alluvium the riparian surface and subsurface are largely decoupled on time scales of months to years; (3) functional classifications of riparian zones intended to support management need to include buried horizons and recognize the limited influence of surface vegetation on subsurface biogeochemistry over short time frames.

title: A Photometric Model of the Inclined F Ring of Saturn
abstract: Philip Nicholson, Joseph Burns, Riccardo Giovanelli Peter Gierasch. Observations by Hubble Space Telescope (HST) of the rings of Saturn during the 1995 ring-plane crossing revealed a surprising asymmetry in the brightness of the east and west ansae. As in historical observations, the ring brightness was nonzero at the time that the rings are observed edge-on. We create a photometric model of the ring system with the F ring inclined to the main ring plane which re-produces the observed brightness of the rings and the asymmetry in ring brightness after the ring-plane crossing.

The F ring is modeled as "ribbon" 60 km tall, of indeterminate radial width, with a gaussian profile of optical depth as a function of height with an equivalent depth of D=10+/-4 km and a full width at half maximum of 13+/-7 km. This is the first estimate of the physical vertical thickness of the F ring, which we find is approximately 1000 times greater than the main ring thickness.

The model shows that as the Earth crosses the main ring plane, the F ring dominates the brightness of the system, and that the asymmetry in ring brightness after the ring-plane crossing is caused by asymmetric absorption of light from the main rings by the front of the F ring.

The model gives post-crossing asymmetries in good agreement with the HST data, but fails to reproduce the small asymmetries in ring brightness observed before the ring-plane crossing. The model profiles of ring brightness plotted vs. horizontal distance from the center of Saturn show many of the features observed in the HST profiles. However, the F ring in this model is longitudinally symmetric, and does not include the many clumps or arcs that have been observed in the real F ring. It therefore cannot reproduce many of the small-scale variations seen in the HST profiles. It may be that these small features are responsible for the asymmetries observed before the ring-plane crossing.

title: Removing Stains at Home
abstract: Many stains can be removed from clothing and household furnishings using the directions in this booklet which have been tested in a Cornell University laboratory. If followed, the chance of removing the stain is very good. There is no single product or method for removing all stains, because the chemical makeup of each stain and agent is unique. Old stains are more difficult to remove than fresh stains, and some staining agents are so strong that they will not react to any efforts to remove them.

title: A Day in Day CareA Program for Two-Year-Olds
abstract: Choosing a good day care program for a two-year-old is a puzzling problem for many parents. Teachers and caregivers, too, wonder about the kinds of activities that are most appropriate for very young children. The following description of a safe and interesting day care program for 2-year-olds can be used by parents as a guide to selecting good day care; it can also be used by a day care center to stimulate discussion

about program planning and implementation. The first section focuses on a chronological order of events from how to manage early arrivals, to snack time, story time, nap time, through to the end-of-day routines, and several other activities in between. The second section deals with selecting equipment, floor plans, and organization. Although the program described here is not perfect, it would meet New York State Department of Social Services day care licensing standards. The most important clue to the quality of a day care program is found in the feelings and the relationships of the people who participate in the program. If parents feel comfortable in the center and trust the caregivers, if caregivers feel valued loved, and if children feel relaxed, happy, and accepted, the foundation for good care exists. 12 illustrations, 3 floor plan diagrams, a short list of suggested books, and a list of educational equipment by area supplement this informative guide.

title: Rethinking Informalization: Poverty, Precarious Jobs and Social Protection
abstract: This book contains a large proportion of the papers initially presented at the conference, "Rethinking Informalizatin in Labor Markets," which took place at Cornell University in October 2002.Globalization, deep economic restructuring, and neoliberal policies have transformed the world of work and labor markets in the North and the South. Contrary to expectations of those who studied the "informal sector" in the 1970s and 80s, the informal economy keeps expanding. This collection brings together an interdisciplinary group of researchers and activists to rethink informalization and the world of work. Together they explore the processes and reasons behind the growth of informal activities and the possibilities for generating decent work and equitable labor markets under the present conditions.
Rethinking Informalization includes papers that examine the heterogeneity of informal activities, the processes that generate its growth, and the lack of concern over increasing economic and social inequalities. Some contributions focus on the need to rethink social protections for labor and the generation of decent work. Others focus on the linkages between informality and poverty, and the final essay focuses on the impacts of informality on the segmentation of urban space and politics.
The volume will be of interest to anyone concerned with the continued growth and dynamism of the informal economy, as well as its pernicious effects on workers lives everywhere.

title: Properties of short channel ballistic carbon nanotube transistors with ohmic contacts
abstract: We present self-consistent, non-equilibrium Green's function calculations of the characteristics of short channel carbon nanotube transistors, focusing on the regime of ballistic transport with ohmic contacts. We first establish that the band lineup at the contacts is renormalized by charge transfer, leading to Schottky contacts for small diameter nanotubes and ohmic contacts for large diameter nanotubes, in agreement with recent experiments. For short channel ohmic contact devices, source-drain tunneling and drain-induced barrier lowering significantly impact the currrent-voltage characteristics. Furthermore, the ON state conductance shows a temperature dependence, even in the absence of phonon scattering or Schottky barriers. This last result also agrees with recently reported experimental measurements.

title: Programming Languages for Scalable Software Extension and Composition
abstract: Large software systems are often constructed by reusing existing code. This dissertation describes several approaches that address the limitations of existing code reuse mechanisms such as class inheritance. The Polyglot design pattern enables software systems to be extended in a scalable way: the code required to extend the system is proportional to the amount of new functionality provided. This design pattern has been used to implement an extensible compiler framework. Nested inheritance is an object-oriented programming language mechanism that supports scalable extensibility in a safer, more natural way than the design pattern approach. Nested inheritance permits modular, type-safe extension of a package (including nested packages and classes), while preserving existing type relationships. Nested intersection extends nested intersection to enable composition and extension of two or more packages, combining their types and behavior while

resolving conflicts with a relatively small amount of code. Nested intersection is implemented in the language J&. The utility of J& is demonstrated by using it to construct two composable, extensible frameworks: a compiler framework for Java, and a peer-to-peer networking system. Both frameworks support composition of extensions. For example, two compilers adding different, domain-specific features to Java can be composed to obtain a compiler for a language that supports both sets of features.

title: Building Successful Digital Repositories
abstract: Ultimately, the success of an institutional repository is dependent on faculty and researchers depositing their materials into it. Using a work practice study methodology and the guidance of a trained anthropologist, Susan Gibbons and others at the University of Rochester, River Campus Libraries undertook an investigation of how an institutional repository may or may not fit into the existing work practices of faculty in different disciplines. Ms. Gibbons shared those findings and suggested ways that an institutional repository can be better aligned with faculty expectations and practices.

title: AgNIC: a Model for a National Digital Library for AgricultureBuilding Collaborative Partnerships Through Technology to Meet Global Needs for Agricultural Information
abstract: With a preponderance of electronic resources readily available as well as technology hardware and infrastructure advancing at a logarithmic pace, the needs for the physical library as a center for research have greatly diminished. Many libraries have moved to the notion of ?library as place,? a welcoming environment for group study, an information commons, and cyber cafes. For those on campus, particularly undergraduates, this new approach has effectively demonstrated increased use of library buildings.
Libraries must also be focused on the notion of ?place as library.? The library?s web presence should provide just as welcoming an environment as the library building for faculty, research staff and students. The sciences, in particular, have embraced the Internet for databases, distributed computing, and virtual collaboration where each member of the workgroup can be widely dispersed, beyond a single institution and, in some cases, beyond national borders.
The sciences have the greatest infrastructure of both digital resources and the newest technologies. New software products make the leap to virtual collaboration, virtual conferencing, and virtual teamwork seamless. Virtual collaborative activities take place in the digital environment, beyond the geographic constraints of the institution. So, where does the research library fit into this new and emerging model? The speaker listed shared some examples, with a focus on agriculture and related sciences, of how libraries can make a difference and provide research support services and an infrastructure for information access, dissemination,

and preservation in the ever evolving digital environment.

title: Digitization of Texas Agricultural Experiment Station Documents for Inclusion in the Institutional Repository and World Wide Access
abstract: The Bulletin of the Texas Agricultural Experiment Station is being digitized, archived in the TxSpace Institutional Repository, and made accessible to a world wide audience. Each page of the original print bulletin is scanned with an OpticBook 3600 book edge scanner and saved as an archival gray scale tagged image file format (TIFF) file at 400 dpi for text pages or 600 dpi for figure or illustration pages. The page images are combined into a PDF document of the pages and optical character recognition generated searchable full text. Dublin Core metadata records are created for each Bulletin and National Agricultural Library Thesaurus subject terms are added to the records. The TIFF files, PDF file, and metadata record for each Bulletin are uploaded to the TxSpace Institutional Repository operated by the Texas A&M University Libraries. In addition to the search functionality of TxSpace the metadata records are harvestable by web crawlers and incorporated in many other web search indexes making them discoverable world wide. This contributed paper will provide details of the digitization, metadata cataloging, and uploading processes.

title: Winnowing the Chaff: Designing and Building a Grain Milling and Processing Web Library
abstract: Kansas State University (K-State) offers a unique curriculum in the milling, baking and industrial (i.e. nontraditional) utilization of grain products. The program targets a diverse audience from academics to amateur bakers to industry professionals to researchers looking at non-traditional fuel and other uses of grains. The range in the audience reflects the multidisciplinary subject areas, ranging from basic sciences (chemistry, biochemistry, food science), applied sciences (baking, milling), engineering (chemical, industrial), business, economics and so on. Given the possible subjects and the variety of audiences, information available on the Internet is widely dispersed and often difficult to find.
Our desire to provide organized access to the above information received additional impetus from the AgNIC Alliance and the request that K-State develop a site for Grain Milling and Processing.
An initial design was developed based on meetings and feedback with faculty in the Grain Science and Industry Department. Subject categories and subcategories were identified and templates for the initial static pages designed. Given the interdisciplinarity of the subjects, it became clear that selected sites could and would appear on several subject pages. Rather than try to update links on multiple pages individually, we investigated our options and selected creating a database as the best solution.
Design of the database led to more standardization of page organization and data elements. The database may be used to generate static or dynamic web pages. A selected site is entered only once, but can be profiled for as many pages as needed. Currently the database provides static pages that are updated monthly. Real time dynamic update of the web pages is in development. We are also developing a search interface for users who do not want to scroll the pages individually for sites of interest.
This presentation will discuss many of the issues we encountered ? issues regarding standards, technology, web usability, selection and display of content, and campus politics.

title: Developing an Electronic Repository for Agricultural Literature (ERAL)
abstract: NAL has been planning and implementing a large scale repository for electronic items. NAL has in place a small electronic repository application (NALDR) containing a few digitized USDA titles including the Yearbook of Agriculture. Concurrently with NALDR, the planning began to create an Electronic Repository of Agricultural Literature (ERAL) of much larger scale and scope. This process has involved a vigorous pilot project involving scientists and laboratories within USDA. The ERAL will include:
? digitized USDA publications, ? peer reviewed articles authored by USDA scientists, ? scholarly presentations by USDA scientists. The process has involved: ? examining available commercial and open-source applications, ? reviewing metadata standards and linkages to existing systems, ? determination of the copyright and intellectual property issues ? enlisting the participation of the USDA scientists ? developing the logistical support for depositing new works ? integrating with AGRICOLA for search, discovery, and dissemination. This presentation reviews the procedure of the feasibility study and the experience of our pilot efforts.

title: Moving Digitization Projects into Institutional Repositories
abstract: Problem- The Lyman Entomological Digitization Project began with a $50,000 grant in the spring of 2003. Drawings, personal letters, hand-written minutes of society meetings, manuscripts of journal articles, historical research, monographs, pamphlets and colour plates formed the initial bulk of the material. Many hours of transcription, changes in the scope of the project, and scanning and editing of documents, consumed the next 18 months. The project stalled at the end of 2005, $22,000 overspent.
Methods- Digital projects on dedicated websites with individual databases managing content need maintenance and regular updating. Standards and best practices for library digitization projects are important, but managing a project within the scope of the budget in order to see preliminary results is paramount. We investigated ways to move unfinished, labour intensive projects into a well-maintained database of institutional research output.
Conclusions- The development of institutional repositories could also include library digitization projects. One database managing many projects and materials that can properly connect to a unique website, the depository search interface or even the library catalogue seems to be the best avenue for managing multiple projects. Problems with overambitious projects and the design and maintenance of a growing number of websites are untenable.

title: Models to predict ruminal carbohydrate and nitrogen supply and nitrogen excretion in cattle
abstract: To mitigate the negative environmental impact of farming, it is important that diets are formulated to accurately match requirements. For that, an adequate characterization of feed composition and its variability is crucial. The original Cornell Net Carbohydrate and Protein (CNCPS) feed carbohydrate and protein fractionation schemes were evaluated and modified to improve predictions of the rumen degradable protein (RDP), rumen undegradable protein (RUP) and microbial protein supply. For carbohydrates, a new expanded scheme was developed; the CA1 is volatile fatty acids (VFA), CA2 is lactic acid, CA3 is other organic acids, CA4 is sugars, CB1 is starch, CB2 is soluble fiber, CB3 is available neutral detergent fiber (NDF), and CC is unavailable NDF. The expanded scheme accounted for more variation in changes in silage quality and non-fiber carbohydrate composition.

The CNCPS and National Research Council (NRC) protein schemes were evaluated using Monte Carlo techniques. Both schemes shared similar limitations including (1) the range of RDP and RUP was over-predicted; (2) the methods used to estimate degradation rates had low accuracy and repeatability, and (3) the assumptions underlying the kinetic models were too restrictive to mimic ruminal digestion. The CNCPS protein scheme was revised and alternative schemes were developed. Predictions of RDP and RUP were improved by assigning rates obtained with the inhibitory in vitro system to a combined insoluble protein B fraction, or by redefining A and B1 fractions as the non amino-N and amino-N in the soluble fraction, respectively.
Urea recycled to the rumen may represent an important source of N for microbes. A dynamic mechanistic model was developed to be used as a component of ration formulation models to predict N recycling to the GIT and urinary urea N. Recycling processes were modeled as positive feedbacks, while renal excretion was modeled as a negative feedback. Both processes were assumed to be regulated by N intake. Model simulations suggested that accurately accounting for urea recycled to the rumen reduces degradable nitrogen needed in the diet, and the use of the NRC 1985 empirical equation to predict urea recycling to the rumen may greatly underestimate recycling in lactating dairy cows.

title: Beyond Reference: New Models for Librarian Involvement in Scientific Research
abstract: Science librarians today increasingly serve users whose research is highly dependent on sophisticated information technology. Providing good service to such users not only involves knowledge of a wide variety of technologies and information tools, but also an understanding of the research process itself. Consequently, libraries are increasingly hiring librarians with expertise in the broad subject areas of their stakeholder communities. In addition to providing reference and consultation services, science librarians? responsibilities may potentially include specialized instruction, non-traditional outreach, and work on special projects to facilitate the research process. The participants on this panel briefly described their varied responsibilities and non-traditional roles, and invited discussion on the topic of librarian involvement in scientific research.

title: UK 101: A New Way of Introducing Freshmen to Campus Libraries
abstract: Personalized Library Portals, Virtual Reference and Federated Searching are some of the recent technological advancements offered in public service at many libraries. At the University of Kentucky, we realized that we needed to "get back to the basics" in order to improve our relationships with undergraduate students. In 2004, the Library Marketing Committee conducted focus groups with undergraduates to provide the data needed to create a marketing plan. The initial goals were to determine the best advertising methods to reach undergraduates effectively and which services we need to focus on first. The sample was small and non-scientific, but the results were consistent in each session. Our undergraduates were missing the most fundamental information about libraries--we provide free assistance and they are welcome at all fifteen campus libraries. In addition, they wanted to know more about the services we offered. During the same year, the Instruction Committee was charged with evaluating the library involvement in a voluntary one-credit course introducing incoming freshmen to the university, called UK 101. The University Libraries had tried several methods, from tours and library exercises for all sections to a dedicated four-week library component for a single section. After reviewing the focus group data, it was clear that a new approach was needed and UK 101 provided an excellent opportunity to reach at least one-third of the incoming freshman class each year. The Instruction Committee and the Marketing Committee collaborated to revamp the course so that it emphasized the basic reasons for using the library and welcomed students to visit the library of their choice. The new and improved library component of UK 101 was required by all sections reaching over 1600 freshmen in 71 sections during the first semester of 2004/2005 academic year. It consisted of a PowerPoint presentation conducted by library personnel, a library tour conducted by the peer instructor and a TILT-based tutorial. The presentation and tour took place during one class period and the tutorial was completed outside of class. The difference(s) between this project and many other library instruction sessions was the heavy emphasis on making students aware of the fifteen campus libraries. The presentation and the tutorial both used fresh and fun approaches to reach the students, and were created based on advice from the Teaching and Learning Center on campus. Due to the strong support of Library Administration, the workload was spread among 25 library employees including librarians, paraprofessionals and library science graduate students. University Libraries has continued participating in UK 101 and anticipates an increased enrollment in 2006. Simultaneously, in an effort to reach the rest of the student population, the Marketing Committee has increased awareness of library services and resources to undergraduates through exhibits at campus events, dorm presentations and advertisements in campus food services and stalls. These experiences have provided the instruction librarians a new way to approach information literacy and produced a foundation of competencies now expected of most undergraduate students.

title: Transforming the Mann Library USDA Reports SystemNew Partners, New Reports, and Historical Reports via a Single Interface
abstract: Since 1995, Albert R. Mann Library at Cornell University has partnered with several agencies with the United States Department of Agriculture to deliver a variety of agricultural commodity reports and datasets via the Web. These partners include the National Agriculture Statistics Service (NASS), World Agricultural Outlook Board (WAOB), and the Economic Research Service (ERS). In 2003, this partnership was extended to include the Agricultural Marketing Service (AMS) and its ~1500 commodity reports issued daily, weekly, or monthly, using a new model of direct delivery of reports by email.
At the time the new AMS reports service was initiated, Mann Library recognized that the traditional labor-intensive posting of HTML pages would not be a viable way to extend an enlarged reporting service into the future. A two-year development effort has created a new back end database and significantly upgraded the web site to improve both content delivery and management, and the new site has been officially scheduled for release in late July, 2006. The new web interface simplifies discovering available reports and data, provides additional metadata including related reports and title changes, and allows patrons to sign up for or change their subscriptions. A new administrative interface allows agency personnel to create or modify titles and descriptions for reports, enter new titles, manage publication dates, and upload reports for immediate distribution.
To further complement recent reports, Mann Library has also undertaken a scanning project to archive historical reports and make them available via the same interface. Approximately 9000 NASS reports dating back to 1919 have been scanned and are available in PDF format via the Mann USDA website, and many more are undergoing scanning for release in the coming year.
Taken together, these changes significantly improve and extend what has already been one of the most significant collections of current agricultural data, and provide both very current awareness and historical continuity of agricultural information via a single point of contact.

title: Defining the nature of a digital conservancyhow diverse collections and systems shape a unified digital repository program
abstract: The institutional repository (IR) is fast being embraced as a necessary service of the academic library. Most often, the IR is implemented as an isolated software system and by definition it contains a limited range of content (i.e., institutionally-produced works). At the same time, non-institutionally-produced digital

collections that the library owns typically sit separately ? perhaps they have special audiences, contributors, needs, and likely they have unique development histories.

What identity unifies them for presentation to users? Do they need to be tied together somehow? Organizationally, how should they be effectively and efficiently managed and preserved? Technically, are there ways to leverage systems to manage diverse collections found in IRs and in subject-based or special collections?

The answer for the University of Minnesota is the University Digital Conservancy, a new program that encompasses data management, preservation, delivery, and the development of new born-digital or previously-digitized collections. This paper focuses on the opportunities and challenges posed by the construction of a holistic framework for developing, managing, preserving, and delivering digital collections. It discusses the complexities involved in: bringing together disparate collections with distinct contributors and audiences; integrating and replacing legacy systems with current technology; developing policy and workflow for digital archival collections, institutional repository-type content, and subject-based repository content that originates in- and/or outside of the institution.

The paper focuses on three examples relevant to the agricultural, environmental, and natural resource sciences, including: AgEcon Search, an existing digital collection of 20,000 applied economics working papers contributed by faculty from around the world; agricultural extension publications; and, works of the new Institute for the Environment at the University of Minnesota. Discussion of the unique opportunities and challenges posed by each of these collections will help inform librarians working to develop their own institutional solutions around digital information.

title: K-5 Kids Use Databases to Learn About AgricultureA State / University / School Initiative
abstract: This presentation addresses our future users by demonstrating a unique program brought to K-12 schools in the state of Delaware. The program, UDLib/SEARCH, can help media specialists and faculty in Delaware public elementary schools teach their children about agricultural research, so that pupils may gain an interest in the future of agriculture and a knowledge of its modern techniques and challenges. These students have the potential to be the university and industry researchers in the upcoming ten to fifteen years.

UDLib/SEARCH, a partnership between the University of Delaware Library and the State of Delaware Department of Education, provides access to networked electronic resources and training for all Delaware public schools. UDLib/SEARCH databases include full-text online encyclopedias and full-text magazines/ journals databases.

Specific demonstrations will be given of appropriate searches, such as biotechnology and cloning, in the elementary school databases Britannica Elementary, Gale Kids?Info-Bits, and SIRS Discoverer. These searches, in turn, will be linked to specific Delaware state curricular standards in educational units related to agriculture, as well as to ongoing programs in the University of Delaware College of Agriculture and Natural Resources.

title: Cooperative Agreements to Build Digital Resources
abstract: The Agriculture Network Information Center (AgNIC) is a voluntary alliance of more than 50 institutional partners who collaborate to bring quality agricultural information to Internet users. Over the

years, AgNIC partners have tried to identify sources of funding to support the building of quality digital content. In 2004 and again in 2005, the National Agricultural Library (NAL) was able to provide small, one-year cooperative agreements to several AgNIC partners for a variety of content-building projects. These projects were envisioned to provide broad access to valuable information and to have mutual benefit to each participating institution and the National Agricultural Library.
The moderated panel session summarized a variety of successful projects funded by the National Agricultural Library / Agricultural Research Service ?mini-grant? cooperative agreement program and encouraged additional participation if future cooperative agreement funding becomes available. * Brief overview describing how the cooperative agreement program originated, the process for submitting proposals, and reporting requirements -Melanie Gardner * Improving Access to USAIN?s State and Agricultural Experiment Station Publications - Claudine Jenda * Digitization of Texas Agricultural Agency Publications in Support of Development of the National Digital Library for Agriculture - Robert McGeachin * Digitizing and Preserving Rare Images of Pathological Disorders of Corn (Zea Mays) and Potato (Solanum tuberosum) - Livia Olsen * Project to Digitize Back Files of the Journal of Rangelands - Jeanne Pfander * Project to Translate into Spanish the "English-only" Terms in the NAL Thesaurus - Janet Poley

title: The National Agricultural Library Customer Information Needs Survey
abstract: The panel discussed the purpose, process, results and implications of the National Agricultural Library (NAL) Customer Information Needs Assessment survey executed in 2006. There were more than 6,000 respondents to the survey, whose results will produce data about agricultural information needs that are expected to be relevant not only to NAL but also to the wider agricultural information community.

title: Implementing the NAL Thesaurus in a Knowledge Repository
abstract: Michigan State University (MSU) Extension currently runs an information management program called the Knowledge Repository (KR). In order to make the KR a useful tool, both for MSU and for others, a decision was made to use the NAL Thesaurus (NALT) as the controlled vocabulary in metadata records for the KR. The NALT is a tool specifically designed for use with agricultural-based information systems and is updated each year. Accommodations have been made to update the thesaurus in the KR to refresh the terms. The system also allows uncontrolled vocabulary to assist discovery of information in KR. The combination allows for broader searching. Although the NALT has been implemented in this instance at MSU, another way to consume the NALT is through the NALT Web Services. Presenters will discuss the MSU implementation of the NALT and the NALTws.

title: Monadic and Substructural Type Systems for Region-Based Memory Management
abstract: Committee: Greg Morrisett (Chair), Andrew Myers, Andrew GallowayRegion-based memory management is a scheme for managing dynamically allocated data. A defining characteristic of region-based memory management is the bulk deallocation of data, which avoids both the tedium of malloc/free and the overheads of a garbage collector. Type systems for region-based memory management enhance the utility of this scheme by statically determining when a program is guaranteed to not perform any erroneous region operations.

We describe three type systems for region-based memory management:* a type-and-effect system (a la the Tofte-Talpin region calculus); * a novel monadic type system; * a novel substructural type system. We demonstrate how to successively encode the type-and-effect system into the monadic type system and the monadic type system into the substructural type system. These type systems and encodings support the argument that the type-and-effect systems that have traditionally been used to ensure the safety of region-based memory management are neither the simplest nor the most expressive type systems for this purpose.

The monadic type system generalizes the state monad of Launchbury and Peyton Jones and demonstrates that the well-understood parametric polymorphism of System F provides sufficient encapsulation to ensure the safety of region-based memory management. The essence of the first encoding is to translate effects to an indexed monad, trading the subtleties of a type-and-effect system for the simplicity of a monadic type system.

However, both the type-and-effect system and the monadic type system require that regions have nested lifetimes, following the lexical scope of the program, restricting when data may be effectively reclaimed. Hence, we introduce a substructural type system that eliminates the nested-lifetimes requirement. The key idea is to introduce first-class capabilities that mediate access to a region and to provide separate primitives for creating and destroying regions. The essence of the second encoding is to ``break open'' the monad to reveal its store-passing implementation.

Finally, we show that the substructural type system is expressive enough to faithfully encode other advanced memory-management features.National Science Foundation, Air Force Office of Scientific Research, and Office of Naval Research

title: Artist Documentation: The Influencing Machine of Miss. Natalijaa
abstract: THE INFLUENCING MACHINE is an interactive installation based on a case history by the psychoanalyst and early follower of Freud, Victor Tausk. In 1919, Natalija A., a former student of philosophy came to Tausk complaining that a bizarre electrical apparatus, which she believed was operated secretly by physicians in Berlin, was manipulating her thoughts. The project attempts to materialize Natalijars hallucinations for the viewer while at the same time alluding to the development of real influencing machines, in the form of radio and television in pre WWII Germany. The installation consists of a large stereoscopic diagram inspired by the mechanics of early television. (The enclosed red/green diagram is a small demo version.) The participant, wearing 3D glasses, looks down at it. Now they see an actual threedimensional structure. They touch a designated space in this virtual machine with a pointer, all at once movies simulating Natalija’s hallucinations appear as projected video clips on a small screen suspended within the space of the diagram. The user takes the pointer away and the projection vanishes. From the moment they don the glasses, the participant enters into a virtual world invisible to those around them, very much as one would when actually hallucinating, (See enclosed tape for a sample of the video).

abstract: I propose to create a "cyber-theatre" where a dialog between the "live" and the "virtual" worlds can occur. The Virtual Web: Interactive Global Spectacle allows everyone to become an artist. The "cyber-theatre" provides the opportunity for the "non"-artist, performer, DJ, VJ or cinematographer to create an original composition in collaboration with other global "artists". Participants will be able to explore the resources and tools they may otherwise not have access to experience. In one moment, there are potentially ten " live" artists in c ollaboration, as well as the unlimited number of" virtual/remote" artists creating this universal, global spectacle simultaneously. Each moment will be a collision and chance meeting of sound, image and movement. This becomes a "living" composition and spectacle because each moment is constantly shifting and transforming. The project will take place in three phases. One can interact seven ways with the "cybertheatre". The "cyber-theatre" creates a venue where a universal visual language can be born. Anyone, anywhere on the globe can experience and interact with the Interactive Global Spectacle* This global collaboration emphasizes the importance of communication and dialog between diverse artistic mediums and investigates the discoveries made when visual art, poetry, performance, technology, music, sound and the Internet collide to create a new visual language that crosses language and geographic barriers.

title: Playlist/Scripts: Nocturne, Opus 23
abstract: <P> Once in awhile, you roll the dice, crack open a fortune cookie, read the tea leaves, or consult a horoscope. Knock on wood, a part of you believes. This eerie underbelly of life, the foggy place where the detective abides, is the setting of Nocturne, Opus no 23, "moonlighting" a 5-minute new media work, which I composed digitally. I shot the full (unedited) DV segment on the road, in the middle of nowhere, while listening to Meringue and keeping Ludvig's Moonlight (sonata) in mind. The footage consists of a night highway, in which the passage of traffic cones, stripes in the road and lights from passing vehicles simultaneously set musical timing while fabricating visually intriguing abstractions. Working in a strictly instinctive manner, I placed events, fabricated stories and wove dreams together, using a detective-like technique – with literary allusions, as well as classic conflicts to juxtapose theoretical and aesthetic aspirations with real world conditions and values. </P>

title: Rockefeller New Media Foundation Proposal
abstract: <P> I am applying to the Rockefeller Foundation to develop an interactive DVD / installation project in which I will explore non verbal thought processes by using the computer to visualize thought."!" is about the moment an idea crosses a person's mind. Aptly expressed in cartoons by a light bulb drawn above someone's head, the moment of awakening or realization ? and the act of making a connection or discovery, is not always a verbal process. The computer makes it possible to exist within ! (PUNCTUM). </P> <P> It is a common occurrence for visual artists to form investigations by means of non-verbal thought processes. It is less usual, yet increasingly appropriate, to use the computer to develop a visual, "virtual" thought. </P> <P> This work will document moments of invention, creation, and conception, from cross-cultural, poly-linguistic and inter-disciplinary samplings. The emphasis will be less about a creation itself, and more about the process, impression, surprise and astonishment of inspiration. Moreover, the project will feature

an attempt to exist within the defining moment itself: to capture a twinkling notion. Like my previous work, it will bring together a wide variety of media. </P>

title: Rockefeller New Media Foundation Proposal
abstract: <P> Visions from the economy of waste is a collection of interactive media pieces that explores what happens when a human by-product becomes a point of convergence between humans and machines. </P> <P> Visions starts with a simple premise: In the near future, technology finds a way to store data in human feces. Cheaper to produce and infinitely renewable, shit replaces computer hard drives, CD-ROMs, and floppy disks as the data storage option of choice. Technology transforms shit from human waste to digital necessity, and makes it a focal point in the information economy. </P> <P> Each of the nine media art pieces explores a particular facet of the future use value of shit. Each piece is based on a fictional character working and living in the new economy of waste. Each piece is created with a specific media in mind that appropriately expresses, in form, content and interactivity, the narrative arc of the fictional characters. </P> <P> When finished, this project is staged as an installation that resemble an exhibit at a natural history museum, documenting the social, political, and technological genealogy of the shit to come. </P>

title: Rockefeller New Media Foundation Proposal
abstract: <P> Mixed Greens is a web-based artwork that uses interactivity to tell a story of the complexities of identity. It will be a mixed genre piece using documentary, fiction,sound, and text. Mixed Greens interweaves two identity stories: of my paternal grandfather and his brothers who, as Irish Jews, lived in a “gray area” between Catholics and Protestants, and later negotiated a different set of identity issues as immigrants in Boston; and that of five lesbians, who live at a contemporary edge of assimilation and difference. Mixed Greens is the third piece in what will eventually be a five-piece/fivecourse meal that I call Queer Feast: a mosaic of contemporary lesbian culture played out through its contradictions of class, ethnicity, desire, and the banality of daily existence. The five pieces/courses consist of: Cocktails & Appetizers (2001), a tale of lust and love, voyeurism and the performance of gender; Mixed Greens, a meditation on identity and assimilation; Bread and Butter, a non-linear “memoir” of the twenty-four year relationship of me and my partner; The Main Dish, a social, historical, and political narrative of lesbian culture; and As American As Apple Pie (1999),

occupying the space between melodrama and sitcom, a tale of lesbian family life. This feast crosses many borders - documentary/fiction/melodrama/comedy, memoir/history/myth, ethnicity/race/class - bringing complexity to the media representation of lesbian life and culture. It also uses interactivity to explore the paradoxes of narrative itself. I will use the Rockefeller New Media Fellowship to create Mixed Greens as well as the Queer Feast web site. </P>

title: Rockefeller New Media Foundation Proposal
abstract: <P> Our project, Information Portraits, is an exploration of the idea that portraiture is no longer 'still life' but can be a form of dynamic distributed network. The Information Portrait project uses new media as a way to augment, converge, and experience representations of self with our shifting patterns in taste and habit. The Information Portrait project consists of three modes toward production: the mobile media studio (a real object), the space of communication (person-toperson), and interactivity (person-to-media). The media performance is the phase in the project during which the materials that make up the Information Portraits are created. The final aspect of the project is the translation of the material developed out of the performances into networked Information Portraits, which are then exhibited on a Web site. The Information Portraits are, in effect, a mapping of various individuals and their neighborhoods. The gesture is to recreate a context while creating a new media experience. </P>

title: Rockefeller New Media Foundation Proposal
abstract: <P> Non-Stop is an interactive kinetic sculpture composed of two flat metal structures on wheels. Both elements are elevated from the floor by approximately 3 inches. The larger part is squared, more stable. The smaller one is more open and appears to be less stable. Each part has a different contour and each shape interacts with the other. The entire piece starts and ends its 'dance1 within a 45 square foot area. Throughout its sequence it expands to engage a 90 square foot area. </P> <P> The movements of Non-Stop are preprogrammed by the author and are altered by the participants. If the participant stops moving so does the sculpture. The work can assume various rhythms and forms. This pace can be modified through the participants' movements. Non-Stop follows a cause and effect as well as a random pattern. After many sequences the participants may come to understand which movements are part of the preprogrammed sequence and which are random ones. As the viewers approach and walk around the sculpture they trigger sensors - connected to electronic circuits, microprocessors, motors , and special mechanisms for the wheels - powered by Photo Voltaic Cells. All these components are hidden in the bottom of the sculpture, (see Draft of the mechanics1).</P> <P> Non-Stop is a large-scale participatory work of art. It attempts to create an antienvironment and through its instability helps the participant to confront conventional assumptions about space and social organization.</P>

title: Identifying Determinants of Antibiotic Resistance in Staphylococcus Aureus

abstract: Staphylococcus (S.) aureus is a leading cause of hospital and community acquired infections. Strains of methicillin resistant S. aureus (MRSA) have emerged that are resistant to all but a few antibiotics, raising the specter of untreatable disease. Indicative of its medical importance, considerable data has been collected on S. aureus, including the whole genomic sequences of several strains with different resistance phenotypes, a diversity of transcriptome data, and a vast assortment of documented observations concerning the characteristics of mutants. These various types of data were analyzed to identify determinants of resistance to four types of clinically important antibacterial agents rifampin, beta-lactams, vancomycin, and daptomycin that target respectively RNA polymerase, key cell wall synthesis enzymes, a fundamental cell wall precursor, and the cytoplasmic membrane. To elucidate regulatory networks, statistically over-represented patterns representing the binding sites of transcription factors were searched for in genomic sequences. To discover mechanisms of resistance, isogenic isolates displaying progressively increasing levels of resistance were sequenced using the method of whole genome shotgun sequencing. By consulting the large body of literature on S. aureus, it was possible to correlate observed genetic changes with transcriptome and phenotypic changes using various statistical methods. The identified determinants of resistance and their potentially complex pleitropic effects are discussed in some detail.

title: The Cornell Digital Reading Room Ergonomics Checklist: Development and Evaluation
abstract: Currently there exists no strategy for evaluating digital radiology reading rooms. This is of concern since the number of symptomatic radiologists suffering from work related musculoskeletal problems seems to be on the rise. Work related musculoskeletal complaints have been shown to be related to workstation set up, chair settings, monitor placement and other issues related to the computer workstation. Due to the visually intensive nature of the work of radiologists working with digital medical images, it is also important to look at factors in the ambient environment, such as lighting. A checklist was developed to evaluate environmental

factors in the work environment of radiologists. The checklist contained 39 questions divided into sections on display screens, input devices, workstation and workstation accessories, chair and ambient conditions. The items in the checklist were taken from checklists and educational material published for example by independent researchers, the Occupational Health and Safety Administration (OSHA) and the Canadian Standards Association. Answer options for each item consisted of factual statements, measurements, rating or a simple description. Some answer options included images for postural comparison. The checklist was not accompanied by a scoring sheet, but items that, if answered in a particular way, could be classified as "Ergonomic Issues" were identified in the checklist instructions and layout. To evaluate the checklist, a mailing survey was sent to practicing radiologists, hospital administrators, ergonomists and other health and safety professionals. In the survey, respondents were asked four questions, both open ended and closed-ended, relating to the usability, layout and overall comprehensiveness of the checklist. The experts were also encouraged to provide general comments on the checklist. Twelve non-factual items or items that required rating or subjective scoring were tested with multiple rater agreement (interrater reliability) and by percent agreement between participants and between participants and an ergonomist. The individual items were tested by asking participants to base their answers based on a series of standardized images depicting a model radiologist performing various tasks, such as reading an image from a computer monitor, use a computer mouse and telephone. Twenty one participants, aged 18-58 years old completed the Interrater reliability - Individual Item Test. Six were male and 15 female. Eight participants were experts, or had background in ergonomics, facility planning and management or similar human-environment relations fields. The Interrater reliability of the items tested was .50 ($p< 0.05$) for the experts, and 0.10 for the novices ($p<0.05$). When the results of participant agreement for individual items were analyzed, four items had consistently lower agreement. Three of these items were modified in accordance with expert feedback and one was excluded from the final version of the checklist. The final version of the checklist contained 43 items. Limitations to this study include the design of the individual item test, not utilizing realistic situation with participants actually observing a radiologist at work, but basing their ratings off images that were not consistent in terms of posture and content. Further limitations also include the limited number of expert feedback received. In spite of the idea that invested experts would provide good feedback, it would prove beneficial to know why some experts chose not to participate. Future research directions include a more comprehensive test of the checklist, both including the entire checklist as well as testing the checklist in actual digital reading rooms. An interesting application of this type of environmental checklist is to adapt it for computer based use, utilizing either portable hospital computer workstations or palm pilots would enable synchronization of information in a centralized facility database as well as instant access to results and possibly feedback. It would be very interesting to see an interactive version of this checklist developed and tested in the future. This is particularly relevant with hospital environments becoming increasingly a digital workplace.

title: Multi-frequency Radar Studies of the High Latitude Mesosphere
abstract: The radar signature of Polar Mesosphere Summer Echoes (PMSE), which are associated with Noctilucent Clouds (NLC) (the highest clouds over the Earth), has been studied using Medium-Frequency (MF), High-Frequency (HF), and Very-High-Frequency (VHF) radars deployed over the central Alaskan region. The echo morphology at the different frequencies is described in case studies wherein PMSE events were observed concurrently using at least two radar systems. The identity of MF and HF radar echoes as PMSE is resolved for the first time by means of simultaneous measurements made with VHF radars, the reference sensors employed traditionally for PMSE studies. Radar reflectivity estimates, derived from in-situ rocket measurements, suggest that HF radars are optimal for the observation of PMSE edge-dominated

type of scatter. MF radars, on the other hand, show comparable reflectivity values for edge and turbulent scattering components, as may be expected for wider antenna beam systems that are exposed to other echo sources. The VHF scattering calculations validate previous research on PMSE, suggesting an increase of the Schmidt number to maintain irregularities of scale sizes in the order of a few meters or less. A large Schmidt number is not needed at MF/HF frequencies since the wavelengths are larger than the Kolmogorov microscale and mesospheric layers can be sustained at low charging levels. Rocket measurements of mesospheric dust content and simultaneous analyzed MF radar backscattered power profiles show a similar type of structure. Dust particles are produced most likely by meteor trails reaching to the upper mesosphere region and may be related to some non-summer Mesospheric-radar Echoes (ME). On the basis of echo duration and signal strength, we suggest that HF radars are most favorable for PMSE monitoring. MF radars show highly organized PMSE layers quite often but are more susceptible to ionospheric absorption and higher altitude returns associated with geomagnetic activity. However, since a number of MF stations are located at polar or near polar latitudes, including Antarctica, it may be possible to use the PMSE signature studied here to investigate its long-term variability as well as its low latitude boundary. The latter could be an indicator of global change.Advisor: Professor Michael C. Kelley Account Number: E70 8353

abstract: This project will take as its primary point of departure my most recent works in which artificially 'intelligent", computerdriven lifelike silicone heads are engaged in improvisational conversations. The conversations which they carry on are neither completely scripted, nor are they random; rather, the software I have written gives each a "personality", a vocabulary, associative habits, obsessions, and other peculiarities, which make their conversations quirky, surprising, and often startling. They also intend to raise questions about computer intelligence and intelligence (and consciousness) itself.

title: 2003 Rockefeller New Media Foundation Proposal
abstract: The Infome Imager is a software for creating visualizations of the World Wide Web. The software allows the user to create "crawlers" (software robots, which could be thought of as automated Web browsers) that gather data from the Web, and it provides methods for visualizing the collected data. Some of the functionality of the Infome Imager software is similar to a search engine such as Google, but with some significant differences. Those differences shifts the software's functionality from being merely a tool for finding information on the Web to an art project which is generating new understandings of the Web. The Infome Imager crawler collects "behind the scenes** data such as the length of a page, when a page was created, what network the page resides on, the colors used in a page and other design elements of a page etc. It scratches on the surface and glances down into the subconscious of the Web in hopes to reveal its inherent structure, in order to create new understandings of its technical, aesthetic and political functionalities.

abstract: Using the highest-resolution satellite imagery available to anyone outside the U.S. or Russian military or intelligence community, I am interested in creating digital images of the monochrome landscapes which represent some of the most vulnerable sites of the 21st century. The landscapes look familiar, even stereotyped - blue (the Atlantic Ocean), green (the Cameroon rain forest), yellow (the Iraqi desert), and white (the Alaskan tundra). But they are produced with instruments and materials (commonplace and yet still extraordinary ones) that in their very construction call into question the material which constitutes a landscape. These landscapes, these images, ask profound questions about their own future -- and ours --even as they adopt the formal strategies of the most abstract, non-referential, 'aesthetic' of the last century's museum pieces.

title: Ceftiofur-Resistant Salmonella Strains Isolated from Dairy Farms Represent Multiple Widely Distributed Subtypes That Evolved by Independent Horizontal Gene Transfer
abstract: Salmonella enterica is a gram-negative, rod shaped bacillus, which inhabits the intestines of mammals, reptiles and birds. In the United States, Salmonella is one of the leading causes of food-borne illness, and is typically acquired through the consumption of contaminated food or water. Modern public health practises have lead to a decrease in the number of Salmonella infections, however, there has been rise in the number of infections caused by antimicrobial-resistant Salmonella.
The rise of antimicrobial-resistant Salmonella subtypes, including the appearance of subtypes resistant to ceftriaxone, represents a particular concern. Ceftriaxone is used to treat invasive cases of Salmonella in children, and is closely related to ceftiofur, an antibiotic commonly used to treat diseases of cattle. In order to develop a better understanding of the evolution and transmission of ceftiofur resistance in Salmonella, we characterized ceftiofur resistant and sensitive Salmonella isolates from seven New York dairy farms. A total of 39 isolates from these seven farms were analyzed for evolutionary relatedness (by DNA sequencing of the Salmonella genes fimA, manB, and mdh), antibiotic-resistance profiles, and the presence of blaCMY-2, a beta-lactamase gene associated with resistance to cephalosporins. Our data indicate that (i) resistance to ceftriaxone and ceftiofur were highly correlated with the presence of blaCMY-2; (ii) ceftiofur resistant Salmonella were geographically widespread as shown by their isolation from farms located throughout New York state; (iii) ceftiofur resistant Salmonella isolated from farms represent multiple distinct subtypes and evolutionary lineages as determined by serotyping, DNA sequence typing, and antimicrobial-resistance profiles; and (iv) ceftiofur resistant Salmonella evolved by multiple independent acquisitions of an identical blaCMY-2 allele and by clonal spread of ceftiofur resistant subtypes.

A collection of 179 human and 166 bovine clinical Salmonella isolates obtained from across New York State over the course of one year were characterized using serotyping and multilocus sequence typing (MLST) scheme based on the sequencing of three genes (fimA, manB, and mdh). The 345 isolates were differentiated into 52 serotypes and 75 sequence types (STs). Serotypes and STs were not randomly distributed among human and bovine isolates and selected serotypes and STs were exclusively associated with human and bovine isolates. A number of common STs were geographically widely distributed, including isolates representing the emerging Salmonella serotype 4,5,12:i:-, which was found among human and bovine isolates in a number of counties in New York state. Phylogenetic analyses supported that serotype 4,5,12:i:- is closely related to Salmonella Typhimurium and that Salmonella Newport represents two distinct evolutionary lineages that differ in their frequency in human and bovine isolates. A number of isolates carried two copies of manB (48 isolates) or showed small deletion events in fimA (9 isolates). Our data indicate that (i) serotyping and MLST typing both provide for sensitive subtype discrimination of Salmonella; (ii) bovine and human Salmonella subtypes represent distinct and overlapping populations; (iii) a number of Salmonella clonal groups, including emerging subtype 4,5,12:i:-, are geographically widespread among human and/or bovine populations; (iv) Salmonella Newport represents two distinct phylogenetic lineages that appear to be host specific; and (v) duplication and deletion events in manB and fimA may provide a mechanism for rapid diversification of Salmonella surface molecules.CSREES, USDA, under NYC-478862 and National research Initiative Award 98-35201-6211 (to L. W.). ILSI Future Leader Award (to M.W.). title: Immobilization of enzymes on inorganic nanoparticles
abstract: Immobilization of avidinylated enzymes (Glucose Oxidase or GOx and Horseradish Peroxidase or HRP) on inorganic particles was accomplished utilizing the affinity of avidin for biotin. We have synthesized biotinylated oxides (layered silicates and iron oxides) via a condensation reaction, and through a simple one step process, we have immobilized enzymes improving their thermal behavior, storage stability and behavior in different pH environments. Furthermore, a profound catalytic activity increase per mass (30-fold) was observed for HRP when immobilized on magnetic iron oxide particles (magnetite particles). This phenomenon proved to be independent of the immobilization steps and was observed even when particles and HRP were simply suspended together in a buffer solution. The activity increase was reversible and could be turned on and off with the addition and subtraction of the magnetic particles (with a Nd magnet). The results were reproduced using different activity assays and different batches of enzyme. Activity assays using particles with increasing magnetic properties showed a proportional increase on the enzymatic activity. The results suggest that the randomly distributed magnetic particles affect the paramagnetic species found in the catalytic cycle of HRP, changing the overall reaction rate. On a different approach modified silicates with immobilized gramicidin were evaluated as delivery vehicles for gramicidin to E. coli bacteria. Also a fluorescent protein immobilized on a biotinylated layered silicate was used to track the uptake of modified silicates to mammalian 9L Glioma cells. Finally, layered silicates and amphiphilic molecules were combined to develop a synthetic biomimetic membrane. The biomimetic membrane has the characteristics of a lipid bilayer membrane with similar thermotropic transitions. To evaluate the membrane's sensing capability, a sensing platform was developed that utilized the biomimetic membrane as the recognition element. The sensing capability was evaluated using saccharin as the analyte, a suspected carcinogen molecule already proven to interact with lipid bilayer membranes in a sensor setup.This work was sponsored in part by the Cornell Nanobiotechnology Center, a Science and Technology Center of the National Science Foundation.

abstract: 25 PIECES OF PAPER is a series of twenty-five interactive and dynamic poems investigating one Edward Guthrie. The project title is taken from a rule of thumb in cultural anthropology that holds that every adult person bom and grown to adulthood in the Western world since 1900 has at least twenty-five pieces of paper documenting their existence. These pieces of paper include birth, baptism, marriage and death certificates, tax identification numbers, school diplomas - in short, all manner of official records use to archive our passage from cradle to grave. Edward Guthrie name once appeared on a birth certificate. When he/I was adopted, that name was replaced with mine.

title: Simple Gifts
abstract: Simple Gifts guides adults to help youth produce items specific for people with Alzheimer's disease. Research shows that people with Alzheimer's may prefer to handle and manipulate things rather than engage in conversation. Sixteen projects ranging from a fleecy muff to a home decorator folder, include detailed instructions and patterns. The program also encourages participants to learn about the disease and become involved in community intergenerational opportunities. If, however, you want to help but are uncomfortable visiting in person, items can be made and delivered to the care facility director ore caregiver. This is a "win-win-win" situation for everyone - the resident, the adult and youth volunteers, and the care facility or caregiver.

title: SINGLE COMPONENT NANOCOLLOIDS AND NANOHYBRID MEMBRANES: SYNTHESIS, CHARACTERIZATION AND PROPERTIES
abstract: Surface functionalized nanoparticles have undoubtedly attracted a great deal of interest in the interdisciplinary fields of nanoscience and nanotechnology. In this thesis two different sets of nano-materials based on surface functionalized nanoparticles are presented. First, single component silicon dioxide nanocolloids (SCN) are nanostructures that exhibit liquid-like behavior in the absence of solvents and preserve the nanostructure in the liquid state. SCNs consist of three main components: a core nanoparticle, a charged oligomer tethered to the core nanoparticle and a canopy that acts as the counter charge to the charged oligomer corona. The individual contribution of the constituents of SCN is studied by surface functionalizing silica nanoparticles with 3- (trihydroxysilyl)-1-propanesulfonic acid, followed by a direct

neutralization of the sulfonic protons by a bulky, tertiary poly(ethylene glycol)-tailed amine. By varying the ratio of the constituents, it is established that the suppression of crystalline regions of the canopy is due to confinement effects imposed by the presence of the surface functionalized nanoparticles. It was also found that at temperatures below the melting point of the canopy, the associated molecular motions at short length scales related to the glass transition of the canopy were hindered due to the electrostatic interaction between the canopy and the charged oligomer corona. Finally, the structure of SCNs is characterized by small angle X-ray scattering. Nafion-nanohybrid membranes as proton conducting materials are developed in the second part of this thesis. Nafion membranes are modified with different protonconducting nanoparticles tailored to add proton conductivity and act as barriers to reduce methanol permeability. A preparation method is presented that produces pliant, elastic, and insoluble in water polymer membranes with homogenous distribution of different nanostructures that influence the morphology of the polymer matrix and its transport properties. The resulting materials showed for some cases an 80% reduction of methanol permeability with comparable ionic conductivities than that of Nafion. Characterization of the nanostructure of Nafion nanohybrid membranes is presented in addition to their transport properties proton conductivity and methanol permeability.

title: New Media Anxiety: Art History and the Problem of Modern Technology
abstract: New media forms intensify the effects of modern technology on both artistic production and its canonical scholarly reception. Indeed, advancements in computational technologies may have transcended the perspective of a mechanical era, ushering in new questions of aura and agency as regards new media versus high art. Both compelling and problematic for their largely military-industrial origins, electronics and the digital stretch the limits of art theory, criticism, and practice. This investigation considers the influence of modern technology upon contemporary artistic production, and how scholars assimilate that art into a cogent intellectual history.

Chapter One introduces a historical context for the canonical reception of advanced technological media. Beginning with the problem of photography and its split nature as both a mechanical tool for 'scientific' observation and an expressive medium for an artist's unique vision, I identify the reverberations of this dualism on subsequent artistic movements and advanced technological forms. Surveying the reception of art and technology in the American academy, this chapter chiefly considers the significance of high art/low culture debates to prevailing canonical responses. Chapter Two brings the dimension of commercialism to this discussion, through an examination of its role in defining the artistic avant-garde. By analyzing the so-called collapse between aesthetic and commercial objects under the duress of capitalism, this writing elucidates the western canon's theoretical apprehensions around electronics and the digital. Chapter Two also considers the impact of postmodern identity politics and social reality of globalization, relative to the foregoing discussions. Chapter Three analyzes what ideological discord is stirred in the coming together of the socially-defined minority artist and media art, especially as it relates to global movements in contemporary production. Finally, it offers a model of embodied engagement with electronics and the digital that brings the intellectual vitality of new media studies to the rich legacy of art history.

This exploration offers a language for art that is deeply engaged with media technologies, and a theoretical bridge that links the resources of recent new media scholarship with dominant western art historical discourses. In analyzing the anxious interface of art and technology, this work acknowledges their symbiotic relationship.

title: Rockefeller New Media Foundation Proposal
abstract: Soft Rains is a robotic installation that miniaturizes and automates the entire film production process to produce a stylish film-noir tale. We will use custom computer software to control small moving cameras, moving set elements, and recorded dialog so that a short narrative can be projected in front of the viewer as they watch. The small, dollhouse scale set allows the viewer to spatially explore what they experience temporally through the video projection. We are interested in using computer technology to investigate what is called "film magic"- the propensity of even the most sophisticated viewer to understand and, at the same time, be drawn in by illusionistic cinematic effects. Soft Rains will create and reveal these effects simultaneously with their product. Newer media is often used to understand the cultural conventions of older forms. The history of industrialization and mechanization has often succeeded in miniaturizing,

streamlining, and automating complex processes. We are interested in both the mythology of progress this presents and in the inherent pathos of its inhumanity. The title, Soft Rains, is taken from a Ray Bradbury story about an automated house that goes through the motions of serving its family, unaware that a nuclear apocalypse has destroyed its inhabitants. Like Bradbury's house, our robotic set creates its story absent of filmmakers and actors, creating narrative without human presence. Our script is also centered upon a search for human presence in an automated environment. Flashbacks and hallucinogenic imaginings are intercut with this simple narrative gesture. Shadowy interiors and tracking camera movements work together to create a noir-like, expressionistic atmosphere. The robotic set will create classic effects'of the genre like the chase sequence, suspenseful cross-cutting between locations, and point-of-view camera shots.

title: VITAMIN AND MINERAL RETENTION AND SENSORY EVALUATION OF EXTRUDED FORTIFIED RICE
abstract: More than 2 billion people suffer from micronutrient malnutrition worldwide. Vitamin A, iron, iodine, and zinc deficiencies are among the leading public health concerns for developing countries, particularly in Sub-Saharan Africa and many parts of Asia. Strict vegetarian diets, lack of diversity in the diet, high rates of infection, and unfavorable socio-economic conditions are risk factors for these deficiency conditions. In India alone, approximately 75% of children under the age of five suffer from iron deficiency, and 57% of children under the age of six suffer from sub-clinical vitamin A deficiency. Micronutrient deficiencies bring adverse consequences to their victims and the economies of the countries in which they live.
Fortification has proven to be an effective long-term nutrition intervention strategy, and rice has emerged as a staple food with much potential as a food fortification vehicle. Rice provides 50% of calories for more than half of the world population. However, a lack of micronutrients in white rice has become a problem for countries with high consumption rates of rice. Low intakes of iron, vitamin A, and iodine are a major concern, while low zinc intake is also a problem. An experimental product, extruded rice kernels manufactured from rice flour fortified with vitamins and minerals, has been proposed as an effective vehicle for delivering a variety of micronutrients to low income populations.
The aims of this study were 1) to select and adapt analytical methods and conduct analyses for vitamin A and vitamin C in the experimental product, as well as measure mineral retention, and 2) to conduct sensory studies to evaluate the acceptability of the experimental product by consumers and compare acceptability by South Asian consumers to that of non-South Asian consumers.
Extruded rice samples fortified with vitamins A and C and iron and zinc were evaluated for their micronutrient retention following extrusion and cooking. The average vitamin A retention in the experimental product after extrusion was 48% for dried kernels and 37% for cooked rice. The average vitamin C retention in the

experimental product after extrusion was 52% for dried kernels and 48% for cooked rice. Iron and zinc retentions both averaged 84% for rice kernels after extrusion (cooked and non-cooked data combined). The vitamin retentions are consistent with studies on vitamin retention in extruded products. However, mineral retention is lower than expected. Larger sample sizes, consistency in analysis methods, and more research are needed to draw further conclusions.

The experimental product was also evaluated for its consumer appeal using consumer acceptance tests. For the acceptability evaluation, two extruded samples of rice (fortified and unfortified extruded rice), and two commercial samples of enriched rice (long-grain white rice) were cooked in a rice cooker and presented to taste panelists. Acceptability of the product was based on a 9-point hedonics test, a just-about-right (JAR) test, and a ranking test. Results suggested greater acceptability by the consumer panel for commercial rice samples. The most sizable difference was seen in the appearance attributes, followed by overall acceptance, and aroma. The addition of vitamins and minerals to extruded rice did not appear to have a large effect on sensory acceptability, with the exception of several appearance attributes. Group differences and group interactions were observed. The South Asian panelist group gave lower scores in several attributes, and the group was generally more critical of (gave lower ratings to) the unfortified extruded rice sample and the parboiled commercial sample than the non-South Asian group. Rice with extruded fortified kernels has potential to be an effective vehicle for fortification in developing countries; however, the challenges in micronutrient retention and acceptability need to be met for optimized utilization.

title: Time Synchronization in Large-scale Networks
abstract: Network time synchronization is an important aspect of sensor network operation. It is often achieved by synchronizing the clock of each node in the network to the clock of some reference node. However, it is well known that synchronization error accumulates over multiple hops. This scalability problem presents a challenge for large-scale, multi-hop sensor networks with a large number of nodes distributed over wide areas.

In this thesis we develop the use of spatial averaging as an approach to mitigating the effects of the scalability problem. We first develop a cooperative synchronization technique using spatial averaging that can achieve "perfect" synchronization in the limit of an infinitely dense network. We show that it is possible to maintain a perfect timing signal with equispaced zero-crossings that occur at integer values of the reference time. Second, we study the benefits of cooperative time synchronization using spatial averaging in networks of finite density. We present a protocol that uses spatial averaging to reduce error accumulation in large-scale networks and show that synchronization performance can be significantly improved by increasing network density.

title: A Proof-Theoretic Approach to Mathematical Knowledge Management
abstract: Mathematics is an area of research that is forever growing. Definitions, theorems, axioms, and proofs are integral part of every area of mathematics. The relationships between these elements bring to light the elegant abstractions that bind even the most intricate aspects of math and science.

As the body of mathematics becomes larger and its relationships become richer, the organization of mathematical knowledge becomes more important and more difficult. This emerging area of research

is referred to as mathematical knowledge management (MKM). The primary issues facing MKM were summarized by Buchberger, one of the organizers of the first Mathematical Knowledge Management Workshop.

-How do we retrieve mathematical knowledge from existing and future sources?
-How do we build future mathematical knowledge bases?
-How do we make the mathematical knowledge bases available to mathematicians?

These questions have become particularly relevant with the growing power of and interest in automated theorem proving, using computer programs to prove mathematical theorems. Automated theorem provers have been used to formalize theorems and proofs from all areas of mathematics, resulting in large libraries of mathematical knowledge. However, these libraries are usually implemented at the system level, meaning they are not defined with the same level of formalism as the proofs themselves, which rely on a strong underlying proof theory with rules for their creation.

In this thesis, we develop a proof-theoretic approach to formalizing the relationships between proofs in a library in the same way the steps of a proof are formalized in automated theorem provers. The library defined in this formal way exhibits five desirable properties: independence, structure, an underlying formalism, adaptability, and presentability. The ultimate goal of mathematical knowledge management is to make the vast libraries of mathematical information available to people at all skill levels. The proof-theoretic approach in this thesis provides a strong formal foundation for realizing that goal.

title: FUNCTIONAL CHARACTERIZATION OF THE CLP PROTEASE SYSTEM IN ARABIDOPSIS CHLOROPLASTS THROUGH REVERSE GENETICS AND PROTEOMICS
abstract: Proteases play an important role in regulating protein maturation, activity and life-time. The Clp protease system in Arabidopsis thaliana plastids accumulates at relatively high levels and consists of a proteolytic core and associated chaperones. The core is an assembly of five different catalytic ClpP subunits, four non-catalytic ClpR subunits, and two ClpS proteins with unknown function. ClpR,S are unique to photosynthetic organisms. Three ATP-dependent chaperones, ClpC1,C2,D, are expected to deliver substrates to the ClpPRS core. Control of Clp activity is not understood and Clp substrates are unknown.

Arabidopsis T-DNA insertion Clp mutants were isolated and genotyped. Null mutants for ClpP4,P5 are embryo-lethal under both auto- and heterotrophic conditions. Mutants of ClpP3,R4 did not form seedlings under autotrophic conditions but developed albino seedlings under heterotrophic conditions, displaying limited greening under low light. Null mutants for the chaperones ClpC1 and ClpD have pale-green and wild-type phenotypes, respectively. ClpP,R core subunits are likely essential, while there are redundancies in the ClpC,D subfamily. Two mutants with partial loss of gene expression for ClpR1 and ClpR2 (clpr2-1) exhibited pale-green phenotypes, with clpr2-1 having a stronger phenotype.

ClpR2 protein accumulation in clpr2-1 chloroplasts was 5-fold reduced, while the ClpPRS core was 3-fold downregulated, suggesting an induction of core composition heterogeneity. Stromal chaperones were upregulated several fold and ClpC was recruited to the thylakoid membrane. Thylakoid protein homeostasis was unbalanced as deduced from increased accumulation of thylakoid proteases, plastoglobules, protein precursors and degradation products. Clpr2-1 chloroplasts were smaller, with 30% less thylakoids than wild-type. Clearly, ClpR2 is not a redundant member of the Clp family and reduced CLPR2 gene expression has adverse effects on plastid and plant development.

A comparative proteome analysis using differential stable isotope labeling of clpr2-1 and wild-type stroma identified 298 proteins, and 113 were quantified. The Calvin cycle was down-regulated, explaining the slower development of clpr2-1. The most striking response was the high accumulation of the chloroplast protein

translation machinery and chaperones. This suggests that the ClpPRS core complex may be involved in regulation of plastid gene expression, providing a first understanding of the functional role of the Clp family in plastids.This work was supported by the grants from the National Sciece Foundation (NSF, #MCB 0343444) and the US Department of Energy (DOE, DE-FG02-04ER15560) to Klaas Jan van Wijk

title: Big Red/Meier white: A Cornell story of architect Richard Meier '56
abstract: This video features Cornell-educated architect Richard A. Meier, class of 1956, founder of the architectural firm Richard Meier & Partners Architects. Created in honor of Meier's 50th Reunion in June 2006, the video is illustrated with vintage photos of Meier's days on the hill, his friends in college, his family, and his earliest projects including his first houses. Meier is heard describing why he selected Cornell, telling about his years as an architecture student as well as his friendships with ZBT fraternity brother Marc Meshorer and Profs Arch and Esther Dotson for whom he did an Ithaca house very early in his career. There is spectacular video footage of his most famous work, the billion dollar Getty Center, combined with voice-over from a 1992 Cornell University lecture by Meier in which he describes his architecture. Meier and architect Peter Eisenman '54 describe the origin of The New York Five (The Whites.) Meier's continued connection to Cornell is described with mention of the design of the new Cornell Life Science Technology Building and with brief commentary and appearances from his Cornell architecture classmates, fraternity brothers, and Cornell friends.

title: Moving to e-Only, Singly and as a Group
abstract: This proposal is for a panel of three speakers to discuss various aspects and implications for converting to e-only journal access. The panel speakers, Bill Kara (Head, E-Resources & Serials Management at Cornell University), Linda Stewart (Life Sciences Bibliographer, Albert R. Mann Library, Cornell University) and Chris Cole (Associate Director of Technical Services, National Agricultural Library) discussed ?e-only? from different perspectives. First, Bill Kara discussed the technical services issues, including staffing, ordering, licensing and record keeping for the conversion of a large number journals in the Cornell University Library to e-only subscriptions. Cornell is currently in the second year of a project with a goal to convert 4,000 current journals to e-only access. Linda Stewart then spoke on Mann Library Collection Development?s approach to selecting journals for e-only access, including the criteria for retaining a journal in print and the impact and feedback the Library has received on its project. Chris Cole then looked at the larger issue of increasing e-only for the library community. His work at NAL to identify active print serial titles in agricultural collections, including identifying duplication and the holders of the last or archival copy. With many libraries actively reviewing their collections and the costs both for materials funding and library staffing and space to maintain print along with the electronic versions, this panel explored some of the major issues and concerns as this trend increasingly unfolds at many libraries.

title: The GlobalAccess2.info Portal: A Flexible Technology For Managing Journal Access Information
abstract: Web-based portals bring together information from many sources and add value to that information by providing a single browsing interface and more consistent display of individual content items. However, designing a portal has typically required developers to pick one or two primary organizing facets at the expense of other valid ones or else face maintenance-intensive cross-referencing between different views of the same information.
A new general-purpose portal technology developed at Mann Library offers greater flexibility for coordinating multiple modes of access to information. Developed originally for the VIVO virtual life science library at Cornell (http://vivo.library.cornell.edu), the Vitro portal technology leverages a flexible ontology structure to link related information and deliver multiple facets or views to a top-level interface. Individual records display in a richly cross-linked structure designed to optimize context for the user while highlighting the original resources gathered together in the portal.
The new http://globalaccess2.info portal provides a common Web presence for a consortium of international programs than provide free or reduced cost access to scholarly journals for developing countries, including AGORA, eIFL, HINARI, INASP, and TEEAL. Resources are equally discoverable by country, by program, by donor agency, by publisher, and by topic area, meeting the needs of diverse users including librarians in the developing world who are potential program participants, staff at the programs themselves, donor agencies, publishers reviewing availability of their own and other services, and librarians in the developing world who have partners in developing countries. A free-text search facility brings up individual entries along with any relevant donor, publisher, program, or country information, allowing users to navigate via multiple independent paths depending on their needs. Detailed content listings at the individual journal level are maintained on the program?s own Web sites and linked at the page level from the common portal.
Over the last 7 months the system that supports both globalaccess2.info and VIVO has been rewritten to promote maintainability and with the hope of releasing the source for use by other institutions. The system is written in Java and runs on the Apache Tomcat servlet container. MySQL is used for back end storage and Lucene is used for full text indexing.

abstract: Professor Zazueta is the Director of the Office of Academic Technology (OAT) at University of Florida (UFL), which provides information technology services in support of the academic mission of the University, including teaching, research, extension and outreach. At OAT, Dr. Zazueta has overseen the successful deployment of one of the nation?s largest enterprise level course management systems, a state-wide video transport infrastructure, grid-based high performance computing resources, and institution of a faculty training program focused on technology. Zazueta has taught and developed UFL courses at the undergraduate and graduate level, including web-based courses and distance education courses using multimedia, and helped launch the Agricultural Information Technology Minor. His reach extends to the international level, where he provides agricultural and biological engineering consultation and participates in university exchanges. In the 1990s, Zazueta led the creation of the IFAS Software Support Office, later folded into the IFAS Office of Information Technology, which was instrumental in accelerating the adoption of information technology by agricultural audiences in Florida.
Professor Zazueta is currently Chair of the Education Division of the American Society of Agricultural and Biological Engineers (ASABE) and Chair of the Information and Communication Technologies Technical Section of the International Commission of Agricultural Engineers (CIGR).
Zazueta received his Ph.D. in Agricultural Engineering from Colorado State University, and both his M.S. (Water Use and Conservation) and B.S. (Civil Engineering) at the Instituto Tecnol?gico y de Estudios Superiores de Monterrey, M?xico.

title: Information Sources for Food Studies Research: Food, Culture and Society
abstract: Food studies is highly interdisciplinary across both science and social science fields. It can include anything pertaining to food and eating from how food is grown to when and how it is eaten to who eats it and with whom and the nutritional quality. Relevant publications are scattered throughout the literature and across academic fields for both current and historical work. In order to truly cover the literature it is necessary to search multiple indexes to the literature. Research in food habits published in the agricultural literature is often as useful as studies of food habits in anthropology or sociology studies. This paper addresses some of the major indexes across disciplines that have citations related to food studies.

title: Impact of Globalization on Rural Communities: Social & Economc Impacts
abstract: Globalization is a hackneyed word and it means different things to different people. For some people globalization is primarily a synonym for global business. Globalization can be viewed as the integration of inputs and outputs into global markets, the sharing of information and knowledge, and the promulgation of rules governing such integration. There are many factors involved in the process of globalization. Transnational corporations are a key factor in the globalization process. The World Trade Organization, International Monetary Fund, and the World Bank do play a role in the process of globalization. The positive and negative affects of globalization and the groups that resist and support globalization are many. Some of the intense effects of globalization can be seen on rural communities, both in developed and developing countries. Corporate globalization has impacted the rural communities in several ways.
These impacts can be categorized into economic, social, political, environmental, and cultural. Of all the rural communities, farmers and rural women are said to be most affected. This panel discussion presents an overview of impacts of globalization on rural communities with special reference to farmers and rural women.

title: Importance of Agricultural Information in the Global Context
abstract: Dr. Mangstl is a specialist in Information and Knowledge Management as well as Agronomy. Prior to joining FAO in 1996, he was Director of the Centre for Agricultural Documentation and Information (ZADI) Bonn, Germany. Earlier, he was Deputy to the Head of the Working Group on Crop Production and Informatics, Center for Life and Food Sciences in Agriculture, Freising-Weihenstephan (Germany).
Dr. Mangstl serves as Director, Library and Documentation Systems Division, General Affairs and Information Department, for the Food and Agriculture Organization of the United Nations (FAO). He is the FAO Focal

Point for participation in the World Summit on the Information Society (WSIS) and related follow-up (C.7 ICT Applications, E-Agriculture).

Dr. Mangstl is in charge of the World Agricultural Information Centre (WAICENT), established by FAO in recognition of the intrinsic value of information in fighting global hunger and achieving food security. Through the WAICENT framework, FAO is able to effectively disseminate the Organization?s vast wealth of information on food and agriculture. The work of Dr. Mangstl?s Division on WAICENT includes capacity building and partnership initiatives which promote best practices in information management, sharing information management systems and tools, e-learning modules for capacity building through the Information Management Resource Kit (IMARK) initiative and proactively participating in FAO?s interdepartmental WAICENT Committee.

Dr. Mangstl has been involved in the Organization?s latest endeavour to effectively transform FAO into a Knowledge Organization. This transformation allows the Organization to learn from and give a voice to the agricultural community regarding a wide range of issues affecting Food Security and Agricultural Production today.

In 2001, Dr. Mangstl was awarded Honorary Professor by the National Agriculture University of Ukraine, Prof. h.c. (UA).

title: OPTIMIZATION OF LIPOSOME-ENHANCED HIGH THROUGHPUT BIOASSAYS
abstract: High throughput analysis is important for the rapid screening or quantitative analysis of large number of samples Microtiter plates provide an excellent platform for high throughput assays and have been used

for decades in immunological and nucleic acid assays. Work focused here on the adaptation of nucleic acid bioassays with liposome amplification in a microtiter plate format with two main objectives: (1) optimization of protein-liposome coupling chemistry and (2) optimization of DNA immobilization in microtiter plates. The protein streptavidin was coupled to COOH-labeled liposomes using 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide*HCl (EDC) chemistry. This procedure was optimized with respect to liposome encapsulation efficiency (total lipid concentration over encapsulated dye concentration) and binding efficiency. For the optimization of DNA probe immobilization in microtiter plates, five different plate types were investigated; medium binding, high binding, NeutrAvidin coated, and two different types of amine binding. Assay protocols for each plate were developed in addition to the ability to immobilize DNA probes and the effect on both the target sequence hybridization and liposome binding. In all cases, data was recorded using a fluorescence plate reader or dynamic light scattering.

Optimal conditions for the coupling of streptavidin to COOH-labeled liposomes were determined as 66% liposomes in MES buffer at pH 7 and a streptavidin concentration of 0.05 mol% of the liposome phospholipid concentration. A coupling time of 15 minutes was sufficient. In the case of the DNA probe immobilization in microtiter plates, a probe concentration of 1 to 50 nM enabled target sequence hybridization in all plates, with a maximum signal to noise ratio (S:N) at about 50 nM. In the case of DNA-labeled liposomes only the NeutrAvidin plates generated a signal, with a maximum S:N of about 400:1. In contrast, for streptavidin-labeled liposomes, the NeutrAvidin plates generated no signal, but the high-binding adsorption plates generated a maximum S:N of about 80:1 (in all cases at 50 nM of target sequence). The covalent binding plates generated a S:N of only 5:1 to 10:1. Following from these results, it is recommended that the NeutrAvidin plate be used with DNA-labeled liposomes to perform a specific test and that the high binding adsorption plate be used with streptavidin-labeled liposomes to achieve a universal assay format.

title: Ecological and Evolutionary Characteristics of Flight-Calls of the Wood-Warblers (Parulidae)
abstract: Many songbirds produce simple, species-specific flight-calls. Some fundamental features of flight-calls remain poorly known, including their functions and variability. I reviewed available information on flight-calls and studied: 1) relationships between calling and weather; 2) seasonal flight-call use in warblers; 3) inter- and intraspecific variation in warbler flight-calls; 4) methods for analyzing flight-calls; and 5) relationships between warbler flight-calls and ecological and evolutionary characteristics.

I examined relationships among call counts, weather, and bird density. I studied flight-calling in warblers during migratory and non-migratory periods. I recorded flight-calls from captive warblers to evaluate inter- and intraspecific differences and quantify variance among species, individuals, and ages and between sexes. I compared three methods to assign calls to caller using discriminant analysis: 1) spectrographic cross-correlation (SPCC); 2) energy-distribution (ED) measurements; and 3) classification tree analysis (CTA) of ED measurements. I used a multi-locus phylogeny to quantify the extent of phylogenetic signal in flight-call spectrographic characteristics. I employed a quantile regression and null model approach to compare interspecific phylogenetic divergence with corresponding spectrographic differences.

I found that: 1) call counts correlated with bird density and weather, but not with weather alone after controlling for density; 2) warblers use flight-calls most extensively during migration, but not exclusively; 3) variation in flight-call properties is greatest among species, with subtle variation among individuals and ages and between sexes; 4) SPCC data yielded the lowest misclassification rates and may best represent individual differences; and 5) in phylogenetically controlled and uncontrolled analyses many energy distribution and syllable structure measurements associated with phylogeny, vegetation density and vegetation height but not with migration strategy, wintering distribution, or morphological characteristics.

Flight-calls are probably more functional as species identifiers than as individual identifiers, and such functions may extend beyond migratory periods. Additionally, phylogenetic and ecological effects occur in flight-calls, and evolutionary histories of structural and signal properties may differ. Species recognition may be important in the evolution of syllable structure, whereas adaptation to environment may be important in the evolution of spectral and temporal properties. Incorporating individual-specific information and meteorological data into acoustic monitoring protocols could increase dramatically the power of these methods.

title: Movement, Survival Rate Estimation, and Population Modelling of Eastern Tundra Swans, Cygnus columbianus columbianus
abstract: The Eastern Population (EP) of tundra swans (Cygnus columbianus columbianus) winters in the eastern United States and breeds from the North Slope of Alaska to the eastern side of Hudson Bay in Canada. EP swans were marked on the wintering grounds in Maryland, North Carolina, Pennsylvania, and Virginia in order to study movements, habitat use, survival, and population structure. Swans were marked with individually coded neck collars (n=1,471), USFWS leg-bands (n=3,504), and satellite-tracked radio transmitters (n=43) from February 1997?March 2002. Location information was collected from February 1997?March 2003 via ground observers, recapture, recovery of dead birds, or satellite location. Satellite-tracked EP tundra swans spent approximately 7 months each year on breeding or wintering grounds, and about 5 months of each year in migration. Significant time spent in migration highlights the importance of migratory habitats to this population. No sub-populations were identifiable based on the exclusive use of migratory pathways, Bird Conservation Regions, wintering grounds, or breeding grounds. Movement rates between states on the wintering grounds (Maryland, North Carolina, Pennsylvania, and Virginia) ranged from 0.00 to 0.46, but were rarely different from 0.25 ($P<0.05$), which suggested that exchange between states caused significant mixing of the population within and between years. Indirect survival rates of marked adult swans ranged 66?84% depending on analytical method or marker type, but were statistically similar (95% confidence intervals overlapped). Use of neck collars in operational marking program is not recommended for future studies due to the cost and difficulty of collecting representative data. To investigate the necessity of annual survival rate estimates, I used data from operational monitoring programs (Mid-Winter Index [MWI], winter ground Production Survey, number of hunting permits, retrieved swan harvest) to develop a model of EP tundra swan dynamics. The model provided reasonable and precise predictions of population size, harvest, and survival. The model can help to predict and understand the effects of harvest on population size. Analyses did not detect density-dependence in recruitment and suggested that a population size goal of at least 80,000 swans can be sustained at current or slightly decreased levels of harvest.U.S. Geological Survey, Cornell University, U.S. Fish and Wildlife Service, North Carolina Wildlife Resources Commission, Pennsylvania Game Commission, Maryland Department of Natural Resources Wildlife Heritage Service, Virginia Department of Game and Inland Fisheries

title: 6.7 GHz Methanol Masers: Properties, Associations and Tracers of Galactic Structure
abstract: The 6.7 GHz transition of methanol is the strongest of methanol masers, and is the second strongest maser transition ever observed in the Milky Way. There is strong theoretical and observational evidence

that the masers trace an early phase of massive star formation. The lack of association of these masers with other astronomical objects such as low-mass young stellar objects (YSOs) and late type stars, and their high brightness temperatures makes them excellent tools to detect and study massive star formation across our Galaxy. The preponderance of massive stars along the spiral arms of galaxies also imply the potential utility of these methanol masers to study the spiral structure of our Galaxy.

In this dissertation, we present a study of 6.7 GHz methanol masers and their properties based on the Arecibo Methanol Maser Galactic Plane Survey (AMGPS), a sensitive blind survey carried out with the Arecibo radio telescope. To carry out this study, we built a receiver for Arecibo that could process signals between 6 and 8 GHz. The high sensitivity of the cooled receiver and the large collecting area of Arecibo made AMGPS the most sensitive blind survey to date for 6.7 GHz methanol masers, and resulted in the detection of 86 methanol masers, 48 of which are new detections.

The distribution of methanol masers as a function of Galactic latitude and the statistics of their multi-wavelength counterparts show our data to be consistent with the hypothesis of 6.7 GHz methanol masers being associated with massive YSOs. Using the detection statistics of AMGPS, we estimate the minimum number of methanol masers in the Galaxy to be 1125. The l-v diagram of the AMGPS sample shows the tangent point of the Carina-Sagittarius spiral arm to be around 49.6 degrees, and suggests occurrence of massive star formation along the extension of the Crux-Scutum arm. A Gaussian component analysis of methanol masers shows the mean line-width to be 0.38 km/s which is more a factor of two larger than what is reported in the literature. We also find no evidence that faint methanol masers have different properties than their bright counterparts.National Astronomy and Ionosphere Center

title: Rockefeller New Media Foundation Proposal
abstract: The Brain Streaming Project presents the means for people to connect and collaborate with one another by using only their brain waves. This non-verbal communication will be represented as a continuously evolving aural and visual expression, accessible to anyone logging on. The Brain Streaming Project will premiere with a one-hour international performance at physical and virtual locations including pocket computers and cellphones at www.brainstrearn.org. The transformed photo booth installations for the premiere performance will remain at each location for participation for the duration of the Fellowship term. For the duration of the performance, participants will be connected to electroencephalographs that amplify and identify their brain waves. The individual logon and brainwave data will be sent to the project server over the Internet, and entered into the server's database. The server then streams this information to the project's Web page, along with sounds and images that change dynamically as new input is received and viewed on touch screen monitors inside the booths, and on the Web. Brain Streaming is a metaphor for universal human consciousness. It reflects our similarities through the transformation of our converging thought patterns into the creation of a collaborative virtual collage.

abstract: The proposed installation will consist of a set pseudo- living objects, each capable of interacting with both each other and the viewer. These objects will be identical and consist of both sensors and speakers enclosed in a ball-like form with a wire umbilical cord to a central controlling computer. The objects will communicate with an ever evolving language that is diverted from the sounds the surrounding objects make and the sounds of the gallery itself. The objects will be able to be "taught" by people directly interacting with them. This will create a "language" that will build from day to day, with a continually changing set of phonemes and sounds diverted from the real world. Each object will develop a personality that will determine how it deals with both input and interaction. Factors that will influence the development of the personality include time of day / routine, type and frequency of interactions, and the personality of the surrounding objects.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: This project is a virtual reality drama, The Trial The Trail, to be presented in an immersive virtual reality system. Imagine Tarkovsky's Stalker, crossed with Alice Through the Looking Glass, crossed with Monty Python and the Holy Grail. Now imagine embarking on a guided journey through this warped yet familiar landscape. As you proceed your actions and interactions are logged, interpreted psychologically, and used to determine the outcome of your quest. The underlying question for this project is: Can virtual reality be as powerful a medium for fiction as novels, plays, film? VR immerses the user in a 3D audio/visual environment which she navigates and interacts with in real time. In fiction, the reader/viewer identifies with a protagonist who is dealing with a challenging situation. It has proven very difficult to bring the two together and make the user the protagonist, navigating a dramatic situation that is rich emotionally, psychologically, sociologically, politically. This project builds on the lessons we learnt creating a previous virtual fiction, The

Thing Growing, and continues our explorations and experimentations in the field of virtual fiction.

title: Rockefeller New Media Foundation Proposal
abstract: I am applying with a series of two projects that I am developing in collaboration with Jacqueline Stevens, a political theorist and author of Reproducing the State (Princeton University Press, 1999) and designer and artist Cynthia Madasky. The first, AgoraXchange, will be a dynamic and accessible online community whose diverse participants will discuss, collaborate, and contribute ideas concerning the game design, the aesthetics, and the politics of the second part of the project, Citizen's Dilemma. Citizen's Dilemma, will be an online multiplayer world that will offer a tangible political alternative to our current world order. In Citizen's Dilemma, all the world's nation-states have been replaced by countries in which political status is no longer determined by birth, and the legal order no longer rewards materialism. We have chosen to use the hugely popular and dynamic form of the online multiplayer game because of its potential for extraordinary detail and elaboration, active and sustained player investment and participation, and timeliness and accessibility as both a medium and social forum.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: I will create two interactive narrative video works comprised of large projections that react to and interact with viewers. Each work presents a silhouette narrative of a prominent Christian Scientist. The first work concerns the events surrounding Mary Baker Eddy's discovering and founding Christian Science in the 1860s. The second presents moments in the life of the American surrealist and Christian Science practitioner Joseph Cornell between 1930 and 1950. The Christian Science faith is best known for it's belief in the power of the mind, and the mind's ability to heal the body of illness - a belief that echoes the ideas of interdependence, emergence and emptiness, that inform my work. Both pieces will be synthetically constructed narratives. The projected imagery will be silhouette performances in the tradition of 19th century magic lantern and shadow theatre. These performances, however, will be algorithmically generated, so that their specific actions and movements are always slightly different. These movements will be rooted in live recordings made on a soundstage and in animations, but will primarily exist as computer models. Viewers will interact with a work when they walk between a projector and a projection on the screen. Viewers' own shadows will instantly become an integral part of the projected scene. They will feel an immediate sense

of presence at a phenomenal level, through the reaction of snow, rain, and scenery to their shadows. Their movements and actions will also have a narrative effect, advancing each work from scene-to-scene in ways that reflect viewers' physical behavior.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: I propose to use the Rockefeller fellowship to develop and expand two parallel tracks: One is life performances Controlling Laser Disk, Quick Time Movies or Camera input with my 5 string MIDI Violin, the other is audience interactive installations. The two activities use similar software, namely "Imageline" "Isadora" and "Jitter." They develop along similar lines of implementation, but use different tool configuration. The Midi Violin Performances are highly scored with mainly pre-recorded image material and depend on innovative, continuously evolving Tools. What started in the 70s as applying my acoustic violin to image control evolved to digital signal control and eventually to digital image processing. As the tools evolve, so does the performance, gradually getting more portable but more equipment demanding. The interactive installations engage a single camera to multiple computer platforms, from 3 to seven. In the first tape sample, there is a demo of a single camera, 3 projectors and 3 computers, in the second a single camera feeds seven computers, applying different software for seven monitors.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: Spectropia is an evening-length interactive media event. Projected on multiple screens, it is performed by two players with the participation of audience members at museums, festivals and public spaces. (A feature film and a home interaction version - combining WD and Internet delivery - will also be created.) Spectropia is a time travel drama set in the future and in NYC, 1931, after the stock market crash. It uses the metaphor of supernatural possession to explore new constructions of subjectivity and the anxieties brought on by consumer culture and emerging technologies. Unlike traditional movies, Spectropia is "performed" interactively using a unique mix of motion sensors, speech recognition and synthesis, and vocal triggers. Audience members, assisted by trained performer/tutors, can use physical cooperation to spontaneously unfold dialogue between onscreen characters; speak to the characters and have them respond; navigate through cinematic spaces; move a character's body; and alter and create the soundtrack. Spectropia has been supported by the Greenwall Foundation, Rockefeller Foundation MAP Fund, Langlois Foundation, LEF Foundation, NECA, NYFA, NEA, the ISA at Arizona State University, and The Banff Centre for the Arts.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: Offshore, an exhibition and website, is the fictional media counterpoint to a non-fiction book I have just completed titled Terra Incognita. Terra Incognita, travels around the world looking at formulaic spatial products in difficult political situations. While generally considered to be politically immune formats of neoliberal magistrates and their business counterparts, these products are also the tools of rogue nations,

cults, and other impresarios. Far from banal, they can become political pawns and even instruments of aggression, storing new myths, desires and symbolic capital in a complex spatial cocktail. Terra Incognita visits six such cocktails: tourism in North Korea, fantastic forms of sovereignty in commercial and religious franchises, high-tech agricultural formations in, automated global ports, microwave urbanism in India's IT enclaves and the global industry of building implosion. These runaway stories, found in the international pages of the newspapers and the global news wires, create something like footnoted fiction in a book of political misadventures.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: This project seeks to examine and develop the technical and artistic means to 'embody' public statues, though the technique of statue projection and animation. This will be possible through especially designed lightweight attachments to the statues, which will support the necessary video- and sound-projection equipment. Images of a statue-animator's face, features or hands will be projected onto the statue's own face, features or hands. The animator's voice, also transmitted to the statue, will thus create a speaking statue, a new communication medium. Unlike the public media we are accustomed to, the animator, animating herself, will publicly engage the other users present, speaking out on any subject they might be concerned about. The animated statue will thus become a vocal - evocative and provocative - agonist, encouraging both onlookers and other participants to respond and develop their own dialogue in real time. Response and dialogue will be possible thanks to the microphones available on the ground that allow the passers-by and any other potential interlocutors to address, interrupt, and question the animated statue while standing before it. A video mini-camera at the statue's head or shoulder will permit the animator to see and hear those speaking to the statue. A particular interlocutor from the crowd may be encouraged to replace the animator, the process continuing in turn as the discussion evolves.

abstract: Transformers will be an installation of absurd devices, which act as a caricature and critique of the promise of new technologies and cultural obsessions with youth, immortality, wealth, health, sexuality, and beauty. Just as more technologies are marketed as 'personal', this piece will be a collection of personalized Rube-Goldberg-like helper/self-help devices organized like a cross between a gym and a tech tradeshow. Devices will be hybrid forms of visceral materials, quasi-familiar objects, and technologies, with a visual aesthetic that aims for the horrifically beautiful. All devices will operate in a personalized way. Some devices will interact with external data from the Internet and some will require the viewer's bodily participation to operate. I hope Transformers will reflect the humor, anxiety, and social transformation that our cultural faith in such real devices and technologies represents.

title: The Effect of Within-host Virus Population Growth and Interspecific Competition on Aphid Transmission

and Population Structure of Barley Yellow Dwarf Virus
abstract: Barley yellow dwarf virus (BYDV) (Luteoviridae) species PAV and PAS are ecologically similar in that they share aphid vectors and host species, but in agricultural fields in New York State we found that the prevalence of PAV was three times greater than that of PAS. To determine if differences in within-host population growth rate affect vector transmission efficiency, disease spread and the distribution of virus types in the host community, this study evaluated the biological characteristics of PAV and PAS species isolates in common agricultural hosts and the outcome of competitive interactions between species in mixed infections. In singly infected plants, PAS population size was 20% greater than that of PAV at 8 days post inoculation (DPI), but by 33 DPI the population size of PAV was 10% greater than that of PAS. In doubly infected plants, by 33 DPI the population size of PAV was 40% greater than that of PAS.
There was no difference in the transmission efficiency of PAV and PAS by Rhopalosiphum padi from singly infected plants at 30 DPI. But when transmission assays were performed 60 DPI, the transmission success of PAV was significantly greater than that of PAS. The greater transmission efficiency of PAV at late stages of infection did not translate to greater spread of PAV isolates in barley, oat or wheat plots in the field experiment. In the field, the susceptibility of plants significantly declined 18 days post plant emergence, suggesting that the development of resistance as plants matured may have arrested virus spread before asymmetry in the distribution of PAV and PAS could occur. In general, disease spread further in wheat than oat or barley plots. Taken together these results suggest that the identity of host species and vector population dynamics in relation to the availability of susceptible hosts are key determinants of the disease prevalence in the host community. Virus multiplication within hosts may influence the relative abundance of PAV and PAS in natural populations if there is a greater likelihood of virus transmission at different stages of host infection.

abstract: Dizzy Atmosphere: Sonic Suspension and Modernist Music is an interactive installation that investigates the interplay between abstract visual art and the cultural resonance and autonomy of the modernist jazz movement. A form of revisionist history, this notion has already been explored via

multidisciplinary pieces that incorporate wall drawing, animation, sound and works on paper. Expanding on my current practice this project will employ the use of a chandelier-like sonic suspension device that utilizes sound as a form of atmospheric or ambient 'light.'Dizzy Atmosphere will shower the listener with an audio experience that is at oncetranscendental, educational, challenges the learned behavior of how we listen, and is interactive by allowing the participant to control experiential time. The audio piece itself will be based on the methodology of musical improvisation, harmonics, and counter-melody coupled with the visual aesthetics of minimalism and formalism. It is my intent to highlight the existence and contribution of early African American abstraction, I attempt a marriage of art history, black history and technology within the domain of the abstract languages they constructed.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: Our proposal is to create an essentially invisible installation that generates music from movement. We propose an installation that will transform body motions into music, while remaining essentially invisible. We will create a play space for social interaction through sound/movement exploration, in which motion detectors record and translate the gestures of one or multiple participants into musical phrases. Different types of movement will elicit different types of sonic response: For example, gestural repetition will be registered and given back as rhythmic patterns. As "players" explore the space like a musical instrument, they find they can engage in a non-linguistic communication. In the absence of visual focus, participants interact with each other instead of with a surface or object. The possibilities for play are not limited by the person's age, education or cultural bias.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: Poet in New York is an interactive non-linear documentary that explores the intersection of new media and poetry, showing the journey of a young Latin American poet in the streets and landscapes of New York. Inspired in the book "Poet in New York" by Federico Garcia Lorca, this project attempts to exhibit the romantic intensity and urban poetics of the most desired city of our time. From Harlem to the Brooklyn Bridge, walking around the alleys of Chinatown and the piers of the West Village, New York turns into a multidimensional city, where each corner portrays a vivid poetic experience, described by Lorca as 'poetic

facts'. The film will be rendered on real-time using a G5 computer, combining 89 short videos, 34 spoken poems and 13 musical compositions, all centered in the figure and daily events of a 26 years old poet in New York. As a result, the viewer will experience a multimedia film filled with emotive scenes, juxtaposing the bucolic interior of the poet and the metropolitan surface of the city. All the content will be combined using a random-based algorithm which comprises 39.338 possible ways to contemplate the movie.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: In September, 2003, I received a commission from the Minneapolis Public Library to develop a public artwork for their New Central Library. The library is designed by Cesar Pelli & Associates; it is currently under construction and is scheduled to open in 2006. The library's commission calls for a project that will use light to "enhance the public's experience of the library." My goal in this work is to create a place where visitors can experience the library as a living ecosystem where books, ideas, and people flow through, exchanging and transacting with each other. Books and periodicals are constantly being taken down from shelves and re-shelved, checked out and returned, searched for and found, acquired and de-acquisitioned. As with earlier works I've made, such as Listening Post (2002), 917: a code without an area (2000), and Passing Through (1996), this piece will be concerned with the movements and dynamics of people and ideas within a specific information system. A library is a place alive with text, some of it sleeping between the pages of shelved books, some of it at play in the minds of readers, some of it at work in electronic card catalog inquiries, lending system transactions, and so on. My piece will explore ways in which these words can be captured on the fly and channeled through an artwork that will reveal the way that words are coursing through the veins of the library. My aspiration is to make a piece that will evoke the ways that language passes through the consciousness of those reading in the library, not unlike the interior voices heard by the angel in Wim Wenders' film Wings of Desire as he walks through the quiet library in Berlin.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: I have recently been invited to create a piece for an exhibit called 'The Brides of Frankenstein' curated by Marcia Tanner for the San Jose Museum of Art, California. This exhibit would coincide with a Bay Area Cyber Art Festival to open in late 2005. I'11 be creating a series of portraits for this exhibit, based on seven women who were practicing science just prior to and during the time of Mary Shelley's Frankenstein. These portraits would also engage the current phenomenon of automatons - spectacular constructions of artificial humans. I believe that as social constructs, as spectacles, and as "monsters," women scientists of the eighteenth and nineteenth centuries shared much in common with these automatons. Most importantly, both were objects of a belief system that saw them as impostors, as threats, and as something less than fully human. These portraits would involve interactive video, incorporating audio with moving and still imagery accessed by touch screen, set into automaton-like armatures. They would be slightly larger than life, yet would evoke an ephemeral quality of existence. Hybrids of the human and mechanical, they would investigate eighteenth and nineteenth century concepts about women, science, machines, and their convergence.

title: 2004 Rockefeller New Media Foundation Proposal
abstract: A food vending cart located in New York City and a game arcade located in Managua, Nicaragua will be employed to establish communication between participants. Both the food cart and the arcade will present the user with a 3D video game; a chat room; and a web cam image. The 3D game will be an on-screen wrestling match that employs the history between Nicaragua and the United States to define the match, a history of intervention and resistance. Although the game will offer at least four characters for the player to choose from, each character will be modeled after specific physical stereotypes from Nicaragua and the U.S. and each character will feature moves/abilities pertaining to the history of that stereotype. Although the game will simulate a wrestling match, it will alternate between free-style wrestling and gift giving depending on the moves made by the user and the capabilities programmed into the game's characters. On screen, as well as playing the 3D game, the players will be able to chat with one another and view one another via web cams (if turned on). Along with the 3D video game, the NYC food-vending cart will feature a typical Nicaraguan meal. Once people play the game they will be awarded with a typical Nicaraguan plate of carne asada, rice and beans, fried green plantain and fried cheese. The meal is punctuated by two cups of coffee: the first is exported coffee which is made from the best bean cultivated in Nicaragua and the second is coffee available in the country, of much poorer quality. The arcade game installed in Nicaragua will be continually available over a period of time and users will have the choice of playing an online competitor in real-time or playing against the computer, when no other player is available. The arcade's exterior will be handcrafted from wood, mimicking traditional Nicaraguan furniture craft. Due to possible connectivity problems in Nicaragua, a project alternative is enclosed.

abstract: The Infome Imager is a software for creating visualizations of the World Wide Web. The software

allows the user to create "crawlers" (software robots, which could be thought of as automated Web browsers) that gather data from the Web, and it provides methods for visualizing the collected data. Some of the functionality of the Infome Imager software is similar to a search engine such as Google, but with some significant differences. Those differences shifts the software's functionality from being merely a tool for finding information on the Web to an art project which is generating new understandings of the Web. The lnfome lmager crawler collects "behind the scenes" data such as the length of a page, when a page was created, what network the page resides on, the colors used in a page and other design elements of a page etc. It scratches on the surface and glances down into the subconscious of the Web in hopes to reveal its inherent structure, in order to create new understandings of its technical, aesthetic and political functionalities.

title: A Day in Day Care: A Program for Two-Year-Olds
abstract: Choosing a good day care program for a two-year-old is a puzzling problem for many parents. Teachers and caregivers, too, wonder about the kinds of activities that are most appropriate for very young children. The following description of a safe and interesting day care program for 2-year-olds can be used by parents as a guide to selecting good day care; it can also be used by a day care center to stimulate discussion about program planning and implementation. The first section focuses on a chronological order of events from how to manage early arrivals, to snack time, story time, nap time, through to the end-of-day routines, and several other activities in between. The second section deals with selecting equipment, floor plans, and organization. Although the program described here is not perfect, it would meet New York State Department

of Social Services day care licensing standards. The most important clue to the quality of a day care program is found in the feelings and the relationships of the people who participate in the program. If parents feel comfortable in the center and trust the caregivers, if caregivers feel valued loved, and if children feel relaxed, happy, and accepted, the foundation for good care exists. 12 illustrations, 3 floor plan diagrams, a short list of suggested books, and a list of educational equipment by area supplement this informative guide.

title: An Evaluation of Best Practices for Effective Public Outreach in Government-issued Methylmercury Fish Consumption Advisories
abstract: Over the last two decades, the United States government agencies responsible for public health have expressed a desire for more research on how to improve risk communication within state and federal fish advisory programs. This charge to risk communication researchers led to the development of a variety of best practices that offer potential solutions to many of the major barriers to effective public outreach. However, numerous studies suggest that government agencies have been resistant to adopting the targeted, interactive risk communication strategies proposed by researchers and that these best practices may have a limited impact in shaping government policy. To date, little is known about the degree to which best practices from the risk communication literature are present in government-issued fish consumption advisories. Further, some health and environmental agencies have expressed that they would be more amenable to adopting the recommendations of risk communication researchers if they were practical and accessible. In order to address these issues, a list of 125 best practices for effective advisory design were compiled from the risk communication literature and adapted into a practical coding scheme that was used to evaluate a sample of 221 government-issued methylmercury advisories. The results of this evaluation revealed a series of gaps between risk communication research and agency practice that are largely driven by conflicting objectives and the inability of many risk communication studies to adequately define effective risk communication. Evaluation is discussed as a means to strengthen ties between risk communication researchers and agency fish advisory programs. Moreover, connections are drawn between the findings of this study and other risk

contexts, raising the possibility that the outsider status of risk communication researchers is less problematic than originally thought.

title: Inciting the Counter-Revolution: Black Neoconservatives in the Post-Civil Rights Era
abstract: Black neoconservatism is one of the most contested political ideologies of the Post-Civil Rights era. As a challenge to mainstream Black political thought, Black neoconservatism enjoys a particular celebrity as the bold new voice in American racial discourse. This thesis critically analyzes Black neoconservative ideology as a counter-discourse: a direct opposition to the liberalism of the 1960s and the legacy of the Civil Rights and Black Power eras.

The emergence of Black neoconservatives as a significant collective in the Post-Civil Rights era correlates with the rise of the New Right in American politics since the election of Ronald Reagan in 1980. The New Right has forcefully disputed the philosophy and strategy of civil rights legislation and the traditional quest for racial equality and justice. Black neoconservatives play an increasingly significant ideological role in conservative politics and public debate in the Post-Civil Rights period. Furthermore, their racial identity lends credence to the New Right's attack on social policy that disproportionately benefits Black people in general and the Black poor particularly. Black neoconservatives dissent from the prevailing convention that racism and White supremacy have become subtle, but nevertheless remain formidable. They insist that civil rights legislation, government intervention and liberal programs have created a pathological dependency among African Americans. Black neoconservatives contend that this dependency is the true cause for the debilitating conditions of the Black underclass and the slow progress among African Americans. Essentially, Black neoconservatives blame the Black Power era for instilling a sense of entitlement among African Americans, and they charge civil rights leaders with profiting from the manipulation of racism.

The core of Black neoconservative critiques is their presumption that African Americans subscribe to a victim-oriented identity that exaggerates the saliency of racism in order to evoke white guilt. They argue that welfare and affirmative action are two bankrupt policies that perpetuate victimization and dependency among African Americans and impede racial progress. As such, Black neoconservatives maintain that self-

help and personal responsibility are the only solutions to the nation's enduring race problems.
Black neoconservatives are presumed to be marginal voices among the vast majority of African Americans. Nonetheless, they are gaining wider currency in the American racial discourse to ultimately shape racial attitudes and change public policy. Furthermore, this thesis posits that Black neoconservatives have taken a political posture that negates the legacy of Black liberation struggles in the United States, which is grounded in an emphasis on Black identity and opposition to racism. Although Black neoconservatives claim their ideology is rooted in the philosophy of Booker T. Washington, this thesis explores the ideology of archconservative George S. Schuyler as a prototypical progenitor of Black neoconservatism. The thesis details the political positions of Black neoconservatives by examining the works of Thomas Sowell, John McWhorter, Shelby Steele, Star Parker, Stephen Carter, Ward Connerly and Glenn Loury.

title: Exploring Effective Education of Family Child Care Providers about Issues Related to Indoor Environmental Pollutants: Training Workshop vs. Printed Material
abstract: Currently, approximately 6 million children have asthma and close to half a million children suffer from elevated blood lead levels, making asthma and lead exposure among the most pertinent health issues facing children in the United States. With a rapidly growing number of children being cared for in child care programs, it is essential for child care providers to be able to maintain a healthy environment. The present study was designed to test the effectiveness of educating family child care providers about indoor environmental pollutants using two low-cost, widely distributable educational treatments. The two educational treatments, a peer educator-led training workshop (n = 14) and a printed, self-study guidebook received in the mail (n = 17), were assessed by measuring participant knowledge of indoor pollutants as well as exposure-reducing behaviors, both before and after the educational treatment. As hypothesized, both treatment groups (N = 31) showed significant improvement in general knowledge of indoor pollutants; improvement on both lead knowledge $t(30) = -2.908$, $p < .01$ and asthma knowledge $t(30) = -2.839$, $p < .01$ post-treatment scores were statistically significant. The second hypothesis that there would be a significant improvement in both treatment groups on child care providers' exposure-reducing behaviors was not confirmed. The third and fourth hypotheses that the workshop treatment group would show significantly more improvement on both knowledge and exposure-reducing behavior than the guidebook treatment group were also not confirmed. This study's findings that the guidebook treatment was as equally effective as the training workshop treatment, suggests that there is great potential for creating positive change in family child care providers' exposure-reducing behavior and knowledge of indoor environmental pollutants using a simple, low-cost method, such as an educational guidebook.Smith Lever funds from the Cooperative State Research, Education, and Extension Service, U.S. Department of Agriculture, under Agreement No. 2005-06-081

title: Numerical Analysis and Experimental Study of Fiber Bundles and Multi-core Photonic Crystal Fibers for use in Endoscopes
abstract: Flexible endoscopes for confocal and multiphoton imaging have the potential to revolutionize the medical field by obviating the need for invasive biopsies; however, these high expectations can be achieved only by reducing endoscope size and by improving image resolution. In this dissertation, methods for enhancing the performance of current endoscopes are explored by studying the properties of multi-core fibers using numerical modeling and experimental analysis. Numerical simulation tools are based on the normal mode expansion of the fields, coupled mode theory, and the multipole method.
Image fibers (multi-core step-index fibers commonly used in fiber endoscopes) have small, closely spaced cores that are predicted through basic theoretical analysis to be strongly coupled. These image fibers are explained to successfully transmit images because of nonuniformities in their cross-section that reduce inter-core coupling. The wavelength, average core size, and degree of variation in core size determine the strength of coupling between adjacent cores, such that fibers with smaller cores at longer wavelengths require more nonuniformity in order for reliable image transmission. Guidelines are given for assessing the performance of image fibers in a particular system. In addition, due to the random nature of this effect, strong core coupling can be observed experimentally, demonstrating that the quality of images from current endoscopes is still compromised by crosstalk.
Multi-core photonic crystal fibers (PCFs) are a potential alternative for use in flexible endoscopes. PCFs achieve tighter mode confinement than image fibers and are therefore predicted to allow higher core densities with less crosstalk and, ultimately, improved image contrast and resolution. The fabrication of these fibers, however, typically introduces nonuniformities into the photonic crystal cladding. Random nonuniformities in the air hole size and location are shown to reduce the coupling length and the coupling efficiency. When the air holes are large, variations in the lattice of less than 1% are sufficient to cause essentially independent core propagation. Nonuniformities are also shown to increase the core birefringence although the dispersion and loss of PCFs are rather robust to variations. Understanding the characteristics of core coupling is a first step towards improving the design of current endoscopes.

title: The Left Periphery, Wh-in-situ and A-bar Movement in Lubukusu and other Bantu Languages
abstract: This study examines the structure of the left periphery, wh-in-situ and A-bar movement in Lubukusu, Kiswahili and Runyoro. It is shown in the study that these languages do not show an argument-adjunct asymmetry. With the exception of 'why', wh-adjuncts can occur in-situ in Islands just like wh-arguments. In addition, Lubukusu in-situ wh-adjuncts, except 'why' give rise to an intervention effect, just like wh-arguments. The unique behavior of 'why' does not reflect an argument-adjunct asymmetry. Rather, it follows from the fact that 'why' is base generated in the left periphery. To the extent that there is no argument-adjunct asymmetry, there is little reason to postulate LF-phrasal movement, contrary to Huang (1982). Secondly, it is shown in the study that 'how' has a syntax that is distinct from that of other wh-phrases. For instance, only 'how' obligatorily agrees with the subject. I argue that this is due to the status of 'how' as a functional head that lacks interpretable phi-features. The fact that 'why' but not 'when' and 'where' also lacks interpretable phi-features suggests that the referential ~ non-referential adjunct distinction should be captured in terms of these features. Thirdly, it is shown that wh-phrases can be in-situ in an object Complex NP, but not in a subject Complex NP. I attribute this restriction to Fiengo and Higginbotham's (1981) specificity condition. Fourthly, the study highlights the differences between relativization of subjects and non-subjects. For instance, while the former triggers wh-agreement, the latter doesn't. These differences are attributed to the location of the feature that drives movement under relativization. In the case of subjects, this feature is located in Fin, but in non-subjects, it is located in Force. The former triggers movement to Spec of FinP, the latter, movement to Spec of ForceP through Spec of PredP. A related issue is the structure of the left periphery. The study shows that the left periphery is more complex than is currently assumed. In addition to the functional projections in Rizzi's 1997 structure, two new projections, PredP and PronP are required. title: Review of grape and wine toxicity research
abstract: The first report of a systematic investigation of toxic substances present in wine was by Leuch in 1895 (9), in which free sulfite was administered in 40-50 mg doses in wine to 150 Swiss human volunteers. Ten per cent complained of gastric distress, increased salivation, and diarrhea. (Sulfite is used in the manufacture of wines for its bacteria-cidal and fungicidal effects.) Investigations of toxicity of wines from that time have centered around the development of liver cirrhosis caused by etha-nol consumption, pesticide residues from vineyard sprayings, and histamine formation in certain wines. Histamine development has been associated with bacterial production occurring when unsanitary conditions are present during wine making, and not with the species of grape. White wines, in general, seem to contain less histamine than red wines (11).

title: Nanofluidic Channels for Biological Separations
abstract: Nanofluidic channels are used to separate DNA molecules by length and applications of the channels to other biomolecules are discussed. The problem of separating DNA and biomolecules by length, charge, or other physical characteristics has consumed a tremendous amount of time and resources over the latter half of the twentieth century and the beginning of the twenty-first century. Micro- and nanofluidic structures afford the opportunity to increase separation effectiveness while decreasing the cost of analysis. Additionally, owing to their simplicity, micro- and nanofluidic devices offer the possibility of modeling molecular motion through confining environments from fundamental physical principles.
Three nanofluidic devices for separating biomolecules by length are discussed herein. A description of their

physical operation is given, and results indicating their effectiveness are presented. Important concepts in molecular biology, polymer physics, and electrophoresis are presented, as well as a review of the trend toward miniaturization of traditional separation techniques. The physical effects manifest in the nanofluidic devices described herein are most easily leveraged in the microchip format, so the details of the fabrication processes used to manufacture these devices are also presented.

title: Soul as Structure: Plato and Aristotle on the Harmonia Theory
abstract: We are conscious beings who think, understand, feel and perceive. We are also material beings composed out of ordinary material stuff. Determining the precise connections between the psychological and the material remains problematic. The harmonia theory is one of the first attempts to frame this as a problem about composite objects. The theory itself is simple: the soul is the harmonia of the material parts of the body. But what a harmonia is and what the theory amounts to are matters of much dispute. I argue that a harmonia is best understood as the structure of the body's material parts.
Plato introduces the theory in the Phaedo, and Aristotle mentions it in On the Soul. In both instances it is roundly criticized. Given that Plato thinks the soul is independent of the body, it is not surprising that he rejects the harmonia theory. However, he has been described as "extraordinarily obtuse" for arguing against the view, since doing so seems to undermine his arguments for a tripartite soul. Aristotle's rejection has been thought equally perplexing, since his own positive view (that the soul is the form of a living body) looks very much like a version of the harmonia theory.
Looking closely at the harmonia theory helps clarify persistent misunderstandings of the view and the reasons Plato and Aristotle reject it. This avenue offers insight into Plato's and Aristotle's positive theories about the soul and its relation to matter. In addition, their rejections of the theory shed light on how they understand the relation between parts and wholes.

The problems lying behind the ancient debate about the harmonia theory are not just historically significant, but also resonate with contemporary discussions about material composition and the metaphysics of mind. Plato articulates a version of the harmonia theory which is perhaps the first expression of a supervenience thesis about the mental, but the precise sort of supervenience at issue hasn't been well understood. But most importantly, whether wholes and souls are causally relevant and whether conscious beings are mereologically simple are issues at the heart of the debate, both ancient and modern.

title: LEADERSHIP COMPETITION AND THE CREATION OF NORMS: A CROSS-NATIONAL STUDY OF WEAPONS RESTRICTIONS
abstract: The dissertation explores the processes through which new norms develop in the field of international humanitarian law. In contrast to most studies in International Relations that examine processes of norm diffusion and socialization, the current work focuses on the early stages of norm emergence. Based on the comparison of two cases of norms against weapons that have a severe negative impact on civilians - antipersonnel landmines and cluster munitions - and several country cases, including the US, France, Belgium, Norway and Canada, the thesis develops a model of the dynamics of norm development that emphasizes the linkages among domestic and international processes aimed at norm creation. The model involves scale shifts from the international level where consensus-decision making stalls progress toward adopting new prohibitory norms, to the domestic arena of different countries where nongovernmental organizations (NGOs) mobilize national support, and then back to the international level where national mobilizations help propel a new negotiating process out of the consensus-based forum. Whereas most empirical studies on norm development and the literature on "new diplomacy" examine NGO activities and negotiation processes at the international level, the thesis pays particular attention to the domestic developments and NGO campaigns, which have been a precondition for a more robust international process. The study argues that the success of norm creation depends first on the initial framing of the problem by NGOs, and second on their ability to foster among states a dynamic called "leadership competition" in which a number of countries consecutively adopt more progressive positions in support of weapons bans. The study emphasizes the important role of individual entrepreneurship and links between NGOs and state decision-makers in promoting new norms regarding weapons restrictions.
Whereas models of norm diffusion focus on the exertion of pressure on states to accept widely recognized norms through the "mobilization of shame," in the current cases support for a newly emerging norm is generated through the "mobilization of pride" and appeals to state identity and ambitions to play important international roles. Thus, the study identifies new processes and dimensions in the creation of norms that have been neglected by the existing literature.Peace Studies Program, Cornell University, the German Marshall Fund of the United States, the Institute for European Studies, Cornell University, the Landesstiftung Baden-Wuerttemberg

title: Natural Vacuum and the flow of maple sap
abstract: In 1967, Blum (1) reported that 43 percent more sap was obtained from closed tubing installations on slopes than from open or vented tubing. He associated this increase with the natural vacuum created in the closed tubing. Gains in sap yield from natural vacuum are especially important, since the collection of sap is the most costly and least profitable phase of making maple sirup. Moreover, sap costs for a tubing network are mostly fixed costs; increased sap flow from natural vacuum represents added profit with little or no added cost. Recently, Laing et al. (6) showed that sap produced with high vacuum differed little in chemical composition from sap produced without vacuum; both yielded sirup of comparable high quality.

abstract: A prime reason for research on the composition of milk is that milk and milk products are vitally important in human nutrition. In addition to milk and milk products being directly consumed, milk components are included in numerous convenience food formulations. Further, the price of fluid milk in New York, now partially determined by its fat content, may, or should be, revised to reflect the nutritional value of milk proteins.

title: Tree-raising on the fruit farm- an essay on management
abstract: "Should I raise the trees myself to replant the North Hill block, or should I borrow the money to buy trees from the nursery?" Many commercial apple growers are asking themselves questions of this sort as they are faced with the large cash investments required for high density plantings. This essay is designed to aid the orchardist in objectively answering such questions. Consideration will be given to some of the tactics of using the nurseryman's skills, to the economics of raising trees on the fruit farm, and to the management factors leading to the final decision on tree purchase or tree raising.

title: Environmental, economic, and physical considerations in liquid handling of dairy cattle manure
abstract: Liquid systems to handle the manure from dairy cattle have been proposed both as economically efficient methods of handling and to alleviate some of the environmental problems associated with the manure. With enough storage capacity to eliminate spreading on frozen ground, a liquid system would tend to reduce runoff of manure during the winter and spring, thereby reducing loss of nutrients and organic matter, which should be of benefit to both farmers and the rest of society.

title: Lakemont and Suffolk Red seedless grapes named
abstract: A major objective in breeding dessert grapes has been to combine the seedless character available in certain grapes of Mediterranean origin with sufficient cold hardiness and disease resistance from our American grapes so that the resulting varieties will be suited for New York conditions. Two major seedless sorts have been found to be the best sources of the seedless character in this program initiated some 50 or more years ago.

title: Cayuga White, the first of a Finger Lakes series of wine grapes for New York
abstract: A changing and expanding grape industry has recently brought about considerable interest in variety evaluation and improvement. This is especially true in the Northeast and Great Lakes area where relatively few pure vinifera or European varieties of grapes are grown. Increasing attention is being given to varieties that will produce premium quality dry table wines of distinctive character. This implies pleasant and characteristic aroma and flavor in wines that are an appropriate accompaniment to a meal.

title: Brighton and Eden-- two new peach varieties
abstract: New York State, on the northern edge of the peach growing area, needs improved varieties of peaches. The best commercial varieties, presently available, are too subject to injury by low winter temperatures to bear full crops every year in most of the fruit growing areas of the State. For this reason, the primary objective of the peach breeding program at the New York State Agricultural Experiment Station is increased resistance to low winter temperatures; that is, increased hardiness.

title: Holiday Strawberry
abstract: Strawberry breeding in the United States began in the middle of the nineteenth century. Most of the varieties released at that time were from private breeders. About 1920, the U.S.D.A. and several land-grant colleges initiated the first large scale breeding programs. Since strawberries vary greatly in their regional adaptation, diverse breeding programs were established. Today, we have specific varieties adapted to various regions. What is a good variety in one region may be of no value in New York.

title: Jonamac- a new apple from Geneva
abstract: Because of this good performance over a 17-year period both in Experiment Station trials and in commercial orchards, Jonamac is introduced as a Mclntosh-type dessert apple, ripening about 8 days before Mclntosh. It is not suitable for processing. Having better red color and better eating quality than Mclntosh, it appears to be best suited to replace some of the Mclntosh apples that are now harvested immature and put onto the market before they are ripe. Jonamac has been suggested as a replacement for Mclntosh. It is offered as a worthy new apple that should be eminently useful both to the commercial grower and to the home gardener.

title: Gender and the Evaluation of Job Applicants in Natural Settings
abstract: Researchers have pointed out that occupational sex segregation will not be fully understood until detailed data are collected on natural (Biernat & Fuegen 2001) and non-scripted interactional settings (Ridgeway & Correll 2004) which are central to gender and employment (Ridgeway 1997). This paper makes a direct contribution to this goal by applying experimentally established theory to a natural environment that involves the live interaction of applicants and evaluators who are recruiting them for jobs.

Gender status theories argue that gender systematically shapes the way men and women are perceived in evaluative and task oriented contexts when gender differentiates actors in the setting (Correll & Ridgeway 2003; Foschi 2000). Specifically, Status Characteristics Theory (SCT) predicts that, in such settings, men will have an advantage over women because individuals hold higher performance expectations for men than for women (Berger et al. 1977; Foschi 1989.) In other words, because there are broadly shared cultural beliefs implying that men at better at the things that count, specific men will also appear more skilled than specific and equally competent women. If these mechanisms are at play in hiring settings, the implication is that employers will be more likely to hire the male applicant even when the female applicant is equally qualified.

Although hiring contexts are almost never accessible to researchers, this project identifies and takes advantage of a unique setting that (1) permits direct observation and data collection on real hiring decisions made in the course of direct interaction and (2) meets the scope conditions of SCT.

The context of this study is the Spanish exam system that is used to recruit candidates to fill important government jobs. Women are currently underrepresented in these positions filling only about 30% of them. Exams to become a government employee in Spain are public and involve the face to face interaction of evaluators and job applicants. Applicants go through a series of qualifying testing rounds; those who succeed at all stages are automatically hired. This setting is exceptional in that: (1) is accessible for direct observation and data collection, (2) the event of interest (i.e. exam) repeats sufficiently so as to evaluate theory-driven claims statistically, and (3) exams are fairly structured, which deems the lack of strict controls less problematic.

I examine quantitative pass/fail exam data and information gathered from direct observation of exam sessions. I use SCT and draw from (and extend) Ridgeway?s ideas about gender and social interaction to make the following predictions. First, following SCT, I predict that (1) male (female) applicants will be advantaged

(i.e. pass at higher rates) in exams involving skills typically perceived as neutral (feminine). Second, I extend Ridgeway?s discussion of gender and interaction, by arguing that (2) the degree of applicant-evaluator interaction will shape the magnitude of prediction one. In other words, larger differences in passing rates between male and female applicants will be observed at exams involving a greater degree of applicant-evaluator interaction than at those exams characterized by minimal interaction. Both hypotheses were confirmed empirically thereby suggesting that (a) SCT appropriately explains the outcome of interest, and (b) the degree of interaction shapes the size of SCT?s predictions. The results of my work suggest that the mechanisms discovered in controlled environments are at play in actual hiring settings. Second, my results also suggest that it may be useful to conceptualize interaction as a continuous measure shaping the size of SCT?s predictions.

title: Factors influencing job satisfaction of lunchroom aides in selected New York State school districts
abstract: Positive psychological and material job satisfaction of employed persons is one primary index of a dynamic occupation. The purpose of this study is to provide data that may be used in development of viable occupations for non-instructional paraprofessionals in New York State school districts. To accomplish this purpose, selected occupational factors are analyzed in terms of their relationship to levels of lunchroom aide job satisfaction, and the satisfaction of significant others (principals and teachers) with the lunchroom aides' job performance.

title: Growing and processing the Wayne apple
abstract: Although several years of commercial experience have revealed some substantial problems in growing Wayne, it nevertheless has outstanding potential when properly managed in the orchard and handled for processing. Wayne cannot succeed if treated as a Greening or Baldwin. It requires the use of some special cultural techniques, as do most standard sorts. Wayne is in season with Mclntosh and may show the same sensitivity to tardy harvest or improper storage conditions. This publication documents the exceptional processing qualities of Wayne and suggests a production system for Wayne that has shown promise at the New York State Agricultural Experiment Station.

title: Peach and nectarine varieties for New York State
abstract: Judicial selection of peach and nectarine varieties is the key to a successful planting. Time devoted to studying the available varieties before planting is likely to be well spent. Variety characteristics, such as yield, quality, hardiness, disease resistance, and market adaptation, should be evaluated in view of your particular site and situation. Cultural practices, weather, and soil requirements involved in peach growing are covered in Cornell Information Bulletin 44, Peach Growing. This bulletin should be consulted before starting a new-peach planting.

title: Jewel Black Raspberry
abstract: The black raspberry is a native American fruit found growing in the wild from New England to the Carolinas. Plants are most frequently found in clearings or around the borders of fields. Early observers collected plants from the wild for planting into gardens where they respond very well to cultivation and freedom from competition. Many early American nurseries offered black raspberries for sale but did not list any varietal names. The first named variety seems to be the 'Ohio Everbearing' which was found by Nicholas Longworth of Cincinnati, Ohio in 1832 and offered for sale. This variety was more or less a novelty because it produced a fall crop. The summer crop was light, berries were small, and poor in quality.

title: Methods and Costs of Distributing Beef to the Food-Service Industry
abstract: The food-away-from-home industry in the United States is a vast and complicated industry. Its size is difficult to measure since the components are so diverse, including not only all commercial eating and drinking places, but also places where food is served as a secondary activity, such as hotels, motels, department stores, drug stores, industrial plants, institutions, planes, trains, vending operations, schools, and military establishments.

title: Cherry Varieties in New York State
abstract: Red tart cherries in New York are almost all of one variety, Montmorency. About two-thirds are grown for freezing and the rest for canning. More than 75 per cent of the State's crop is harvested by machine. Mechanical harvesting has been facilitated by the use of ethephon to loosen the fruits. The cherry industry, however, has had setbacks by low prices, high labor costs, competition from other cherry growing areas, hurricanes just before harvest, killing spring frosts, and cold, rainy weather during bloom.

title: Composition of experimental New York State grape brandies
abstract: Although New York State has no brandy distillation industry, it is possible that distillation may be developed in the future with increased grape and wine production and availability of considerable quantities of other fruits. A preliminary experimental distillation study on New York State wines was reported a few years ago from this laboratory (1). It was shown that a beverage brandy with desirable aroma can be produced from New York State's major grape, the Concord. It was suggested that brandy distillates should be prepared at the highest possible proof in order to reduce the presence of undesirable varietal aromas. As a series for study, we selected several of the major varieties of grapes grown in New York State and prepared brandy distillates by means of small laboratory-scale distillation equipment. This report summarizes the study on chemical constituents and organoleptic quality of the New York grape wine distillates.

title: Fruit varieties in New York State: Berries
abstract: There are many good small fruit varieties available for home garden or commercial planting. The wide climatic variations and soil types within New York State influence the performance and recommendations on varieties. Nurserymen, commercial growers, processors, chain store buyers, and home gardeners all have definite ideas about the relative importance of different varietal characteristics.

title: Rural Development: An Emerging Social, Economic, and Demographic Imperative
abstract: America is passing through a social, economic, demographic, and technological evolution that is "unhitching" the rural development process from the modern agricultural development process. The purpose of this paper is to analyze some major dimensions of this trend and relate the implications to emerging opportunities of land-grant universities, government agencies, and business enterprises for broadened public service to rural modernization.

title: Apple rootstock problems and potentials
abstract: This publication is designed to assist the grower in anticipating problems which can occur with higher density orchards; such anticipation should enable the grower to avoid these pitfalls, to minimize the total effects of shortcomings, and to maximize the total utilization of the potential of modern orchard design. The rootstock-related problems described should not be interpreted as negating the value of dwarfing rootstocks and high density plantings.

title: Community Reaction to Education Change
abstract: Change in public education is a continuous process. Though the pace of change may be an issue of some persons criticize the public schools for lagging in the face of needed reforms, while others see the schools as changing too much of the evidence over a long period shows that schooling tends to reflect the temper of the times. New curricula, standards, pedagogy, or modes of organization emerge regularly in response to changes in the society as these are reflected in
demands on public education.

title: 1973 Sweet Corn Control Report

abstract: All tests were conducted in Ulster County, New York. Growing conditions in the spring of 1973 were characterized by exceedingly heavy rainfall; cold, wet soils; and cool temperatures. Due to these conditions, all plantings which were to be utilized for first brood borer tests yielded very poor stands and had to be replanted. Therefore, all tests were directed at second brood borer, corn earworm, and fall armyworm.

title: 1973 European red mite control evaluations
abstract: Although six species of tetranychid mites have been reported as attacking apple in New York, only the European red mite, Panonychus ulmi (Koch), is at present of general economic concern. Occasionally, the two-spotted spider mite, Tetranychus urticae Koch, is troublesome late in the growing season. Such infestations, however, are sporadic and localized. Acaricidal evaluations in 1973 were conducted only against the European red mite.

title: Resistant rootstocks for new York vineyards
abstract: The grape industry in New York is interested in establishing new vineyards of both old and new varieties. Because there are not enough choice sites available, some will be replantings of old vineyards, others may be on shallow soils. To assume success in such situations, there is a need for vines grafted upon resistant rootstocks.

title: Burgundy- An early fall, dark red apple
abstract: The Burgundy apple (N.Y. 161) originated from a cross made by R. C. Lamb in 1953, Monroex N.Y. 18491 (Macoun x Antonovka). A population of 357 seedlings from the cross was field planted in May 1955. As the seedlings came into fruiting several years later, their fruiting performance was evaluated. This particular seedling ripened its first fruits on September 10, 1960 and was selected by R. D. Way in 1961. Nineteen other superior selections were also chosen from this same population. This is a much higher proportion of good clones selected from a progeny than is usually chosen, indicating that this was an especially good parental combination.

title: Feasibility of fall armyworm, Spodoptera frugiperda (Smith) control on late-planted dent corn
abstract: During the late summer of 1973, fall armyworm populations were abnormally high in the Hudson River Valley, and the resulting severe defoliation to late-planted dent corn caused much concern to producers and extension service personnel. Due to the ragged appearance of the plant resulting from larval feeding, a heavily infested field can be quite alarming. Many inquiries were received at this laboratory pertaining to the necessity of applying control measures to combat this pest.

title: Highland- a new winter pear
abstract: Highland was selected from a progeny of 119 seedlings of a cross of Bartlett x Cornice made in 1944 by Dr. George Oberle. It first fruited in 1956 and was selected by the author for further test. In 1963, it was made available by the New York State Fruit Testing Cooperative Association for testing under the number, N.Y. 10274. It has continued to look promising, and numerous growers who have tested it have reported favorably on it. So, it was decided to introduce it in 1974. The name, Highland, was chosen following the tradition of naming pears after New York State place names. Highland, in the center of the Hudson Valley fruit area, is the location of the Hudson Valley Research Laboratory which has a long record of service to growers in the area.

title: On the Wagner-Anantharam outer bound and achievable Gaussian source coding exponents
abstract: Tightness of the Wagner-Anantharam (W-A) outer bound, for the quadratic Gaussian two-terminal source coding problem, is examined. The proof of the sum rate constraint for the rate region of this problem provides some hints on possible looseness of the bound. We prove tightness to the rate region for this setup, by first proving tightness for the many-help-one problem with conditional independence. We also look at the performance of the W-A bound and find the worst choice of the auxiliary random variable X, appearing in the expression of the bound, for the sum rate constraint.
In the second part of this work, the Gaussian point-to-point source coding problem is considered. The error exponent for this problem was presented by Ihara and Kubo. We generalize the Gaussian method of types, introduced by Arikan and Merhav, and use Marton's approach to retrieve the best achievable error exponent for this setup. Our method is readily extendable to more complex Gaussian source coding problems.

title: Counting Caring: Accountability, Performance and Learning at the Greater Ithaca Activities Center
abstract: This dissertation -- incorporating action research, global ethnography, narrative inquiry, and critical race perspectives -- examines an agency-wide staff and organizational development process at the Greater Ithaca Activities Center (GIAC), an African-American-led, multicultural community center in Ithaca, New York, while contextualizing this local work within an examination of global structural forces shaping the work of the community-service sector as a whole in the United States.
Through this research project, we explored how a sustained collective, critically reflective educational process linked to concrete action could help GIAC and its staff respond simultaneously to external demands for improved accountability and internal desires to improve programming. In this dissertation, which draws upon that research, I suggest that an unarticulated tension between two fundamentally different conceptual frameworks -- a dominant "professional public management" frame and a contesting "personal relations" frame -- reflects and shapes how people understand, and thus, attempt to account for, learn about and improve "community service" work. I examine the ways these contesting frameworks played out in practice, demonstrating how seemingly "objective" approaches to accountability and evaluation -- e.g., the now nearly ubiquitous outcome measurement model -- actually marginalize important kinds of work and reproduce entrenched social (dis)advantage. I explore the challenges and possibilities faced by an agency that centralizes

a "personal relations" perspective in a world dominated by norms of "professional public management," and I examine practitioners' efforts to not only reflect on, but collectively respond to contesting perspectives on their work within social environments shaped by institutionalized relations of power. Finally, I argue that taking a "personal relations" perspective seriously is needed to (a) understand GIAC and organizations like it on their own terms; (b) re-imagine accountability and evaluation as dynamic, dialogic, collective processes that can enable people to learn about and improve their work in the course of learning about what matters; and (c) revitalize a weakened public commitment to nurturing human potential and embracing diversity, thus reinvigorating our community-service system as a whole. From a methodological perspective, this dissertation also exemplifies action research strategies for collaborative knowledge creation and draws lessons from this work for the further development of action research praxis.

title: Computational and Analytical Perspectives on the Drift Paradox Problem in a Freshwater Embayment
abstract: Small, planktonic organisms in a variety of fresh and saltwater environments with primarily unidirectional flow often manage to avoid washout into a larger, often inhospitable body of water, a phenomenon commonly termed the `drift paradox.' We investigate the drift paradox in the case of vertically migrating zooplankton in a long, narrow embayment emptying into a colder lake by means of a three-dimensional hydrodynamic model, SI3D, along with an accompanying (modified) particle tracking module. Chapter 1 describes tests of SI3D designed to insure that the basic advection and scalar (temperature) transport behave as expected in the embayment regime. Chapter 2 describes simulations using different migration types, zooplankton cloud sizes, start times, and background flow speeds. Largely due to its interaction with exchange flow between lake and embayment, background flow speed emerged as the most important factor influencing the residence time of the zooplankton, with smaller flow speeds, normal migration, and larger zooplankton clouds typically leading to higher residence times. Chapter 3 discusses similar smulations, with the addition of rooted macrophytes, which are represented in SI3D by changing the amount and height of drag in the channel. Flow rate was again the single most important variable, with the interaction between flow and zooplankton cloud size also significant. Chapter 4 describes the results of attempts to represent the advection of zooplankton undergoing vertical migration by a relatively simple partial differential equation, with the goal of approximating the results of Chapters 2 and 3. The equation contains advective and diffusive terms with the velocity term encompassing the water flow as well as zooplankton vertical position in the embayment. Background water flow, assumed homogeneous in time and longitudinally, is obtained by averaging output velocities from SI3D. A simple distance/rate approximation was also investigated. While the analytical models can be useful in situations involving a simple flow field, when more accuracy is needed, or in case of a vegetated channel, using the full computational model is advisable.

title: 1974 insecticide research report in cabbage maggot, seedcorn maggot, aphids on lettuce, and phytotoxicity in cucumbers
abstract: Each year we conduct extensive insecticide screening tests for control of the cabbage maggot (CM), an important soil pest of crucifer crops. Diazinon, a phosphate pesticide of limited persistence, is this State's single recommended material for CM control on direct-seeded cabbage and root crops; although with root crops it is necessary to suppress H. brassicae for the entire growing season which requires extended persistence. For transplanted cabbage, diazinon, Guthion, and Dyfonate are the recommended materials.

title: The Costs of Seasonal Agricultural Employment
abstract: For years an argument for excluding hired farm workers from the unemployment insurance program was what the seasonal nature of agricultural employment would make the program too costly. A recent 15-state study of the feasibility of agricultural coverage indicated that average cost rates for agriculture would not be substantially different from cost rates in nonagricultural industries. But, it did support the contention that costs for seasonal agricultural labor are substantially higher than costs for nonseasonal agricultural labor (2,3).

title: Factors affecting chemical thinning of apples
abstract: The necessity for fruit thinning is generally accepted. While limited hand thinning is still practiced in some areas, Northeast fruit growers rely almost entirely on chemical thinning. In some years, as much as 85 per cent of the apple acreage in New York State is chemically thinned. This practice is inexpensive and effective, but the results are not always totally satisfactory. Complete failures (little or no thinning or

drastic overthinning) are rare, but the variability in results may exceed the limits of expediency. The factors that contribute to this variability can be conveniently divided into six categories as follows: initial fruit set, variety, materials and rates, time of application, physical factors that affect the application of the material and its absorption, and physiological factors that affect the response of the trees.

title: McIntosh Apple Crop Prediction Grower Sampling Instructions
abstract: Apple fruits grow at a relatively uniform rate during much of the season. While many factors influence the rate of fruit growth, such as weather, tree vigor, crop load, etc., the interacting effects of these factors are fairly well established 2-3 months after bloom. Throughout the remainder of the season, the growth rate follows a predictable pattern. As a result, the harvest size of Mclntosh apples can be accurately predicted from fruit size measurements on August 1.

title: Fiber Facts
abstract: This information bulletin explains the unique properties of all the common fibers on the market today, Acetate and Triacetate, Acrylic and Modacrylic, Cotton, Linen, Ramie, Hemp, Lyocell, Nylon, Olefin, Polyester, Rayon, Silk, Spandex, and Wool. Learn which fibers make up brand names like Lycra, Creslan, Cordura, Tencel, Thinsulate and Dacron. Fiber origin, production, characteristics, producers, care, cautions and other issues are addressed for each fiber. A great gift for children going off to college, wedding showers, or for housewarming.

title: Experimental Wine Production
abstract: A major portion of the wine research program at the New York State Agricultural Experiment Station, Geneva is concerned with the evaluation of grape varieties for suitability for wine production in New York. The viticulturalcharacteristics of each variety or selection are assessed in the Experiment Station vineyards by the staff of the Department of Pomology and Viticulture, and enological evaluation is done by the Department of Food Science and Technology. In order to evaluate the enological merits of each variety, a wine production procedure suitable for small batches (1 to 50 liters) has been developed. The goal of wine production for this program is to obtain a consistently sound wine representative of the varietal potential. Presently, over 500 experimental lots are produced annually. This report describes the standard procedure used to produce these experimental wines.

title: The Institutional Dynamics of Health Care Reform: Organizational and Class Dimensions of Policy-Making at the Columbia-Presbyterian Medical Center, 1911-1998
abstract: Dissertation Committee: Dr. Richard F. Bensel (Chair), Dr. Theodore J. Lowi, Dr. M. Elizabeth SandersFollowing the lead of Theda Skocpol, Jacob Hacker and other neo-institutionalists, this dissertation draws attention to the private and voluntary components of America's mixed systems of social insurance and health care provision. What distinguishes my approach is a closer view of institutional politics and policies, as well as an emphasis on their reciprocal connections with the larger political process. Drawing on the extensive administrative archives of the nation's oldest medical center, Columbia-Presbyterian Medical Center in New York, I reconstruct and analyze some of the formative moments of the American health care system.

Two broad conclusions concerning American health care politics emerge from my analysis. First, academic medical centers, as well as private health care institutions more generally, make policies and shape health care politics. Thus, private institutions are policy-makers, in a very real sense. Second, private institutions of health care provision have participated in the making of health care policy not as monolithic, autonomous institutions but as internally contested and externally invested organizations. On the basis of my research, I propose a new theoretical framework which brings into view the organizational and social dimensions of health care politics that have been previously overlooked. The framework builds on two theoretical approaches - the neo-Durkheimian theory of micro-classes and the theory of intersectionality - to reveal a coherent set of political subjects and structures involved in health care politics. Central to this framework is a concept of 'institutional class positions,' which links the mechanisms of bureaucratic power and occupational control with the effects of gendered and racialized systems of inequality to produce an integrated, dynamic understanding of institutional processes. I show that the organizational and social structures which shape these positions have far-reaching political effects, indicating the limits and possibilities of health care reform in the predominantly private framework of health care provision.

title: USING STABLE ISOTOPE PROBING TO IDENTIFY SOIL MICROBIAL POPULATIONS INVOLVED IN PHENOL METABOLISM AT AN AGRICULTURAL FIELD SITE
abstract: Dr. Eugene Masden, Dr. Anthony HayThe global distribution and universal toxicity of phenolic compounds make their degradation of great interest. The goal of this field study was to provide insight into three distinct populations of microorganisms involved in in situ metabolism of phenol. Our approach measured 13CO2 respired from 13C-labeled phenol and stable isotope probing (SIP) of soil DNA at an agricultural field site. Traditionally, SIP-based investigations have been subject to the uncertainties posed by carbon cross-feeding. By altering our field-based, substrate-dosing methodologies, experiments were designed to look beyond primary degraders to detect trophically related populations in the food chain. Using GC/MS, it was shown that 13C-labeled biomass, derived from primary phenol degraders in soil, was a suitable growth substrate for other members of the soil microbial community. Next, three dosing regimes were designed to examine active members of the microbial community involved in phenol metabolism in situ: (i) 1 dose of 13C-phenol, (ii) 11 daily doses of unlabeled-phenol followed by 1 dose of 13C-phenol, and (iii) 12 daily doses of 13C-phenol. GC/MS analysis demonstrated that prior exposure to phenol boosted 13CO2 evolution by a factor of 10. Furthermore, imaging of 13C-treated soil using Secondary Ion Mass Spectrometry (SIMS) verified that individual bacteria inc orporated 13C into their biomass. PCR amplification and 16S rRNA gene sequencing of 13C-labeled soil DNA from the 3 dosing regimes revealed three distinct clone libraries: (i) unenriched, primary phenol degraders were most diverse, consisting of ?-, ?-, and ?-proteobacteria, and high G+C Gram-positive bacteria, (ii) enriched primary phenol degraders were dominated by members of the genera Kocuria and Staphylococcus, and (iii) trophically-related (carbon cross-feeders) were dominated by members of the genus Pseudomonas. Furthermore, fungi-specific PCR amplification and sequencing of the 18S-28S internal transcribed spacer region genes from soil-derived, 13C-DNA revealed a number of fungi involved in phenol degradation at this site. 13C-labeled fungal DNA was only detected in one of our treatments (that representing trophically-related carbon cross-feeders) which suggests that these organisms are potentially secondary consumers in phenol-degradation at this site. These data show that SIP has the potential to document population shifts caused by substrate pre-exposure and to follow the flow of carbon through terrestrial microbial food chains.National Institute of Environmental Health Sciences

title: Using Sticky traps to monitor fruit flies in apple and cherry orchards
abstract: Sticky traps can be used to monitor the presence of adult fruit flies in cherry and apple orchards. The traps utilize both color and odor to attract the flies. It has been known for some time that the flies are attracted to the color yellow. Consequently, sticky board traps now used are colored yellow. The flies are also attracted to red and this color has been used on sticky spheres to monitor the apple maggot flies. Odor is the second stimulus. Household ammonia placed in bottles was a common attractant used in early sticky boards. The ammonia had to be changed frequently and the process was time-consuming. Today, the traps use Hy-Case Amino and ammonium acetate mixed into the sticky material on the traps. This attractant lasts several weeks under orchard conditions and lengthens the interval between trap changes to 2 to 3 weeks.

title: Simplified rearing and bioassay for the seedcorn maggot, Hylemya platura (Meigen)
abstract: Before 1926, Leach (7) was able to rear larvae of the seedcorn maggot (SCM), now known as Hylemya platura (Meigen), on potatoes or beef extract agar inoculated with the causal organism of potato blackleg, Erwinia atroseptica (van Hall) Jennison. Since then, attempts to maintain colonies in the laboratory have met with limited success because of low egg production until McLeod found that protein was essential for oviposition (8). Harris et al. (5), using the information of McLeod, was able to establish a productive laboratory colony of SCM. Although excellent results are obtained with this technique, procedures are somewhat time consuming. A simplified technique has been developed at the Geneva Experiment Station which produces large numbers of SCM for use in laboratory studies."?

title: LIBERTY, a new disease resistant apple
abstract: At first, the objective of this project was resistance to apple scab only, but it soon became clear that when apples were grown without any chemical disease control, the other major diseases (cedar apple rust, fire blight, and mildew) could be more serious. Thus, the objectives were broadened to include resistance to these diseases as well. In 'Liberty,' we have an apple that has a measure of resistance to all four of these diseases. Our experience so far is that it can be grown without any fungicidal sprays. Since it is not resistant to insect, however, spraying or other means of insect control must still be used.

title: Growth of European Larch at Five Spacings
abstract: Restrictive economic conditions and increased knowledge have led foresters to question traditional spacing of forest trees and to conduct research that would test their assumptions. Numerous studies have confirmed that when forest trees are widely spaced, the branches, crowns, and stems are larger. Although the stem form of all trees is changed, the height of conifers may be little affected. An immediate economic benefit is derived from lower planting and precommercial thinning costs. Later, although early stand basal area and volume growth may be reduced by wide spacing, more rapid growth of individual stems can produce more merchantable volume, a shorter rotation, reduced logging costs, and better financial returns.

title: The onion maggot and its control in New York
abstract: The onion maggot, Hylemya antiqua (Meigen), is the most important insect pest of onions in Canada and in the northeastern and northcentral United States. This pest first reached North America from Europe in 1841, and since that time it has frequently devastated onion crops. It is particularly severe in New York where crops can be destroyed completely if no steps are taken to protect them. The insect can develop resistance to insecticides very quickly; many compounds recommended in the past had to be abandoned because they ceased to be effective against the pest. Also, there is evidence that the onion maggot is beginning to develop low but significant levels of resistance to several of the currently used insecticides. The insect's ability to develop resistance to insecticides threatens the production of onions grown commercially in New

York and other states. Since very few new compounds are becoming available, there is an urgent need to use every possible practice that might help to alleviate the problem and to develop alternative control measures which can be integrated with the still effective chemicals.

title: Examination of the Multi-Source Interference Task
abstract: Masters ThesisThe Multi-Source Interference Task (MSIT) was developed to examine the neural networks associated with attention and cognitive interference. The MSIT combines different types of interference known to delay reaction time for the purpose of maximizing cognitive interference. The MSIT has been shown to produce activation in the anterior cingulate cortex, a region of the brain implicated in processes of executive attention. Previous work has not addressed the separate influences of each source of interference. This study was designed to decompose the sources of interference to determine their independent contributions. Participants were instructed to identify the number that was different in a three digit array. Font cue, flanker, and spatial interference factors were evaluated. Additionally, blocked versus mixed design was compared. It was found that trials with one type of interference were easier to resolve than trials with two types of interference. Further, the presence of a target font cue diminished interference. Blocking was also found to yield faster response, but only in trials with minimal interference. Finally, trials with congruent types of interference were more difficult than trials with incongruent interference. Results of the study can be used to design a maximally potent MSIT.

title: Apricots for New York State
abstract: Apricots are a delicious fruit that probably would be grown more commonly if they were less frequently damaged by low winter temperatures and late spring frosts. Like peaches, the dormant blossom buds of apricots are frequently killed by temperatures of -23 C (-10 F) or warmer. Also apricots bloom earlier than peaches and are more frequently injured by late spring frosts.

title: A STUDY OF BARSTAR FOLDING EVENTS USING BOUNDARY VALUE SIMULATIONS
abstract: This study revolves around a computational algorithm called SDEL (Stochastic Difference Equation in Length) that generates approximate protein folding trajectories on the atomically detailed resolution scale. The protein studied is Barstar- a barnase inhibitor. Because of the protein?s interesting structure (four alpha helices, three beta strands) and relatively small size (89 residues), Barstar is an optimal choice for running complete folding trajectories on a computer. 12 pathways were generated with SDEL, starting from a structurally wide selection of unfolded conformations, yet all ending with the native configuration. We tracked hydrogen bonds, dihedral angles, native and non-native contacts, and energetic along these folding pathways. The resulting trajectories show: 1) Barstar follows the Hydrophobic Collapse folding scenario, 2) native ?-helices begin forming earlier in the trajectory than the ?-sheets, 3) particular residues maintain a propensity for helical structure in their unfolded state, and 4) specific non-native contacts persist during the folding trajectory. Strong correlations were found between the SDEL pathways and data from NMR, CD, and other experimental studies.

title: CHARACTERIZATION OF ROOT-KNOT POPULATIONS FROM RICE-WHEAT FIELDS IN NEPAL AND REACTION OF SELECTED RICE AND WHEAT GERMPLASM TO MELOIDOGYNE GRAMINICOLA
abstract: Root-knot nematodes (Meloidogyne spp.) are important pathogens and can cause significant yield losses on rice and wheat. However, information on the biology and impact of these nematodes on the productivity of rice-wheat systems in Nepal is limited. Identity of 33 isolates of root-knot nematode collected from rice-wheat fields throughout the production regions in Nepal was determined using morphometric measurements of larvae, perineal pattern analysis of mature females, host range tests, symptoms observed on infected roots, and internally transcribed spacer region sequences. Results obtained suggested that all the collected isolates of root-knot nematode were M. graminicola, with minor variation in larval measurements, perineal patterns and ITS sequences between isolates collected from the hill and Terai regions. Also, significant variation in the aggressiveness of the isolates was observed on the rice cultivars Labelle and LA 110. In addition, a significant variety by isolate interaction was observed in selected rice and wheat germplasm tested. Generally, root-galling severity and reproduction of the isolates of M. graminicola were higher on rice than wheat.
Greenhouse experiments were conducted to verify an effective protocol for assessing the reaction of large number of rice and wheat germplasms for resistance to M. graminicola. The effects of inoculum density, inoculation methods, size of planting container, incubation time, and planting seeds or seedlings on the infection and reproduction of M. graminicola in rice and wheat were determined. Based on the results of

these tests, the protocol adopted for screening rice and wheat germplasm for resistance to M. graminicola was planting seeds in 10- cm pots filled with pasteurized soil (500 cc) infested with 2 or 10 eggs of M. graminicola/ cc soil, and then incubating for 60 days in a greenhouse at 25 C.
The reaction of 150 and 74 germplasms of rice and wheat, respectively was assessed by determining the root-galling severity and reproduction of the most aggressive isolates of M. graminicola. All the rice and wheat germplasms tested were susceptible to M. graminicola. However, significant differences in the level of susceptibility of rice and wheat germplasms were observed, as suggested by the ranges in root-galling severity and reproductive values recorded.

title: 2005 Rockefeller New Media Foundation Proposal
abstract: The Trial The Trail is an immersive virtual reality (VR) experience designed to engage the user as a central protagonist in a compelling interactive drama. It is designed for a projection-based, 3-D stereo VR display with one large screen or multiple screens forming a virtual theater. Immersive VR puts the user inside the virtual world with the other characters rather than outside, viewing the world on a monitor and manipulating an avatar of herself. This collaborative project brings together artificial intelligence and visualization research with the goal of creating intelligent actor-agents and interactive, dramatic, virtual reality experiences. Our interactive drama is designed to create an unfolding story around the user which the agents establish, populate, maintain and influence. We build our VR dramas using a two part structure; a psychological substrate where we explicitly determine the emotional states we want to evoke in the user; and an implementation level with three elements - an interactive script, a smart set, and actor-agents – that turns the psychological plot into a dramatically evolving series of responsiveconundrums for the user.

title: Between State and Transnational Community: U.S.-Japan Technoscientific Diplomacy in Earth Observation
abstract: This dissertation examines intergovernmental collaboration in science and technology. In particular, it ventures into a new area of theoretical and empirical inquiry by investigating how scientists and engineers, working on behalf of different states, built an international remote-sensing system and created knowledge about the earth in the absence of the shared social, political, and cultural resources that would have been made available by a shared state or other shared authority, such as an international organization or treaty regime. In contrast to two prominent interpretations of scientific activity in the international arena, namely science as an idealist epistemic community and science as a Hobbesian imperial endeavor, the dissertation

offers an explanatory interpretation that accounts for the creation of scientific knowledge and the development of international order by analyzing U.S.-Japan collaboration in remote sensing as a kind of international negotiation that I call "technoscientific diplomacy." Through this technoscientific diplomacy, U.S. and Japan scientists and engineers, working on behalf of their governments, accomplished something that had never been previously accomplished: they developed and operated in near-real time a space-based remote-sensing instrument, its ground data and information system, and an international political economy of scientific data, all under the management of two states.

title: Patterns of Pesticide Use on New York State Produced Sweet Corn
abstract: Sweet corn is one of New York's most important vegetable crops being grown on about 1,700 farms (Fig. 1) and representing 11.4 percent of total vegetable cash - receipts. New York ranks first among states in the production of summer season fresh market sweet corn and seventh in the production of sweet corn for processing. Although the acreage for each is about the same, sale value for fresh market is about 2.8 times that of processing. Statistics on production, value, and utilization of New York state sweet corn are presented in Table 1.

title: A Review of Cabbage Pest Management in New York: From the Pilot Project to the Private Sector, 1978-1982
abstract: Although a number of major pests attack cabbage in New York, insects are the most important. Two lepidopteran larval pests that begin to attack cabbage early in the season are the diamondback moth and the imported cabbageworm. The cabbage looper, a lepidopteran migrant from the south, arrives late in the season and usually becomes an additional threat. Cabbage maggot, flea beetle, cabbage aphids, and onion thrips are other insect pests that warrant control measures. Cabbage is also sporadically infected by diseases such as black rot, black leg, downy mildew, club root, and sugar beet cyst nematode, any of which can result in substantial crop loss.

title: Strawberry Cultivars for New York
abstract: Choice of cultivars is one of the most important and difficult decisions the strawberry grower has to make. To read a typical nursery catalog, all strawberry cultivars are equally "superior" to all the rest. Obviously, it is not that simple. The relative performance of different cultivars can vary enormously. Some cultivars will easily yield twice as much fruit per acre as others, but may or may not prove acceptable for the end use of the buyer. There is a bewildering number of strawberry cultivars commercially available, and new cultivars are being named every year. To make matters even more complicated, each cultivar can vary in its performance from region to region, from year to year, and even from farm to farm. Lastly, the relative value of different cultivars is inherently subjective. People naturally differ in their appraisal of flavors, and growers assign different levels of importance to different characters such as productivity versus firmness versus quality.

abstract: Two projects are proposed that look at computer data as a malleable construct and suggest possible

directions for what a fictional data type might be in the context of artistic based representations. The first work Walking is a dynamic light based installation that involves the representation of a series of 1 dimensional computer data streams as a series of 1 dimensional representations over time as rhythms of light and uses physical objects to bring meaning to the computer rendering of this handmade fictional data. The second work Weather Projection is a web based work that internally starts with the data of a few descriptive words that define he circumstances in a distant location and magnifies and exaggerates these words to the extreme point of creating a personal narrative movie (with the help of the viewer). These two works are at opposite ends of a spectrum that is defined by the complexity of the transformation used to represent a piece of data.

title: Learning the Lay of the Land: Needs Assessment for a Community Environmental Approach to Obesity Prevention
abstract: Over 60% of adult Americans are now considered overweight or obese. This is of special concern to women because post-menopausal obesity may increase the relative risk of developing breast cancer by as much as 40%. Until recently, efforts to address the problem of obesity have centered on technical rational education and individual behavior change models. However, population-level solutions are necessary to address public health problems such as obesity. A population-level approach requires attention to both physical and social contexts within the community. In order to better understand the contexts from within which individuals make health behavior decisions, this study asks: How do community members perceive the role of the social and physical environment on overweight and obesity, and on their own eating and physical activity behavior? The thesis is that those social and physical environmental factors do influence the perceptions of community members.
A qualitative, constructivist approach in partnership with members of the community of focus was used in an attempt to answer the research question. The study objectives were 1) increased understanding of community members? perceptions of the way the physical and social environment for healthful eating and active living affect their decisions about eating and exercise, and 2) development and testing of methods for conducting a community environmental assessment. The assessment was conducted over an eight-month period in a rural New York town where over 60% of the adults were overweight or obese. Using a participatory, collaborative approach with Cooperative Extension partners and a local cancer coalition, the assessment included a study

sample of 25 adults identified through purposeful and snowball sampling. Methods included 17 individual interviews, two focus group discussions, community observation, and photo elicitation.

The assessment process revealed a profile specific to a unique population and context. Data were revealed that illustrate the role perceptions of environmental influences play in eating and exercise decisions in the context of a local community. Constructs from both theory and public health practice contributed to study methods that facilitated a deeper understanding of community members? perceptions of local context and provided an important lens through which to view the health environment in the community. The study revealed data that illustrate three key themes. First, ownership of obesity is seen as both an individual and a collective problem. Second, there are conflicting goals for food and physical activity in the community. Third, there is a relationship between the social and physical environment that has not been addressed in existing models. These three key findings add an important dimension to the understanding of context within which individuals make eating and exercise decisions.

These results suggest that a community environmental assessment can be a useful strategy for understanding how the physical and social environments can affect health behavior. Learning the lay of the land requires a contextual view from both the physical and social perspectives of community residents. This study demonstrates that these perceptions can be captured and provides an important foundation for exploring locally tailored, community-based approaches to obesity prevention. More research is needed to provide both theoretical refinement and testing of this methodological approach to improve community nutrition practice and policy.Funding support for this project was provided by the U.S. Department of Agriculture/ Cooperative State Research, Education and Extension Service (USDA/CSREES).

title: Root Rot of Snap Beans in New York
abstract: Root rot is a major disease on snap beans and occurs throughout the bean-growing areas in New York. Over the years, monoculture of beans, improper crop rotations, and increased soil compaction have intensified the prevalence and severity of bean root rot. Economic losses due to this disease have been considerable although they are variable among fields during the same growing season, and in the same field from year to year. Generally, root rot is most severe and causes the greatest damage to beans when cool and wet weather occurs from seeding time to about three weeks after planting, followed by hot dry weather.

title: Assessing the Risk of Grape Berry Moth Attack in New York Vineyards
abstract: Research on assessing risk of grape berry moth (GBM) damage is the result of questions raised by New York State grape growers about: (1) the possibility of reducing expenditures on insecticides, (2) the possibility of treating only problem areas within vineyards, and (3) why the grape berry moth (GBM) is such a problem in some areas and not in others. Our objective is not to make decisions for growers but to provide the information and methods necessary for the grower to decide what solution for berrymoth control is best for a particular vineyard and financial situation. That is the purpose of studying risk assessment for the GBM. The following are some observations we have made that show the differences between high-risk and low-risk vineyards and a method is presented that may be used to determine what the actual levels of GBM are in particular vineyards.

title: Effect of Winter Storage on Thrips Damage to Cabbage
abstract: Approximately 30% of all cabbage grown in New York State is stored and sold during the winter and early spring. This practice ensures a continuous supply of cabbage for cole slaw, fresh market, and other purposes throughout the winter, and allows New York growers to compete with the fresh crop grown in the southern states in winter and spring.

title: Laboratory Rearing of the Imported Cabbageworm
abstract: The imported cabbageworm (ICW), Artogeia rapae (L.) is one of New York's most serious pests of cabbage; studies related to its control are an important component of our research program. For instance, we have experimented with the use of a granulosis virus for management of ICW, and our laboratory has an ongoing program screening cole crops for resistance to several lepidopteran species including ICW. Because these studies all require a constant supply of disease-free eggs and larvae, we continuously rear the insects in the laboratory. Fortunately, although the ICW is a crucifer specialist, it can be reared on a wheat germ-based diet. The major requirements for successful culture are: (1) supplemental lighting in the greenhouse to provide conditions suitable for mating and oviposition, and (2) strict attention to measures designed to prevent disease in the population, and to prevent microbial contamination of the diet.

title: Sweet and Tart Cherry Varieties: Descriptions and Cultural Recommendations
abstract: The 1985 Orchard and Vineyard Survey by the New York State Department of Agriculture and Markets listed 257 sweet cherry orchards in New York State with total acreage estimated at 1,073 acres. Cultivars being grown include 'Bing', 'Chinook', 'Compact Lambert', 'Corum', 'Emperor Francis', 'Gold', 'Hedelfingen', 'Hudson', 'Lambert', 'Napoleon', 'Rainier', 'Sam', 'Schmidt', 'Stella', 'Ulster', 'Van', 'Vista', and 'Windsor'. 'Emperor Francis' is the leading sweet cherry variety in New York comprising 20 percent of the total trees, with 'Hedelfingen' (16%) and 'Schmidt '(15%) also of importance.

title: Thermomechanical behavior and microstructure evolution of tantalum thin films during the beta-alpha phase transformation
abstract: Thin tantalum films were prepared on oxidized silicon substrates in the metastable b phase using an ultra-high vacuum sputter deposition system. Stresses that arose in the films due to interactions between the film and substrate during thermal cycles from room temperature to 700?C were measured using an in situ substrate curvature measurement system, allowing oxygen content to be controlled during both deposition and thermal cycling. X-ray diffraction experiments were used to determine crystal phase and orientation before and after cycling. The transformation from the b phase to the stable a phase takes place in conjunction with a distinct jump in stress in the tensile direction. The magnitude of the jump and the temperature at which it occurs were strongly affected by the amount of oxygen to which the film is exposed and whether the exposure took place during deposition, between deposition and thermal cycling, or during thermal cycling. Increasing oxygen content inhibited the phase transformation, requiring higher temperatures to complete it. It is shown that the phase transformation must occur by thermally activated hopping of atoms across the phase boundaries, and it is proposed that oxygen added to the system inhibits the transformation by slowing boundary motion through solute drag. The microstructure of phase-transformed films were studied using electron backscatter diffraction (EBSD). A unique, previously unobserved microstructure was found, characterized by smooth, continuous gradients in crystal orientation of up to 4?/mm over distances of up

to 6 mm within individual grains. Rotation axes were analyzed using rotation pole figures and compared to those of dislocation arrays that could cause such orientation gradients to occur. The addition of oxygen during deposition was found to have a large effect on the microstructure, leading to much larger grain sizes, lower angle grain boundaries, and smaller orientation gradients within grains.

title: CULTIVATING THE NICHE: A STUDY OF THE ORIGINS AND CONSEQUENCES OF STANDARDS-BASED CERTIFICATION ORGANIZATIONS IN THE U.S. ORGANIC FOOD INDUSTRY
abstract: Standards-based certification organizations (SBCOs) as a source of market order have been largely neglected as a topic of study by social scientists, particularly when compared to other sources of order such as the state and the market. This dissertation presents three papers that examine the origins of SBCOs, their impact on broader regulatory structure, and how they influence market entry and exit rates in the U.S. organic food industry.
The first paper, ?Fences and Gates: An Inductive Case Study of Standards-Based Certification Organizations in the U.S. Organic Food Industry,? employs qualitative evidence to develop a typology of SBCOs and then quantitatively assesses what facilitating conditions led to the founding of distinctive SBCO forms in U.S. states. Findings from this paper suggest that the codification of standards and certification processes initially served as a ?fence? that established a boundary around the concept of organic but which subsequently served as a ?gate? by which industry outsiders entered the organic industry and engendered endogenous field-level change, significantly altering the trajectory of the market.
The second paper, ?Mechanisms Generating Variation: Regulatory Change in the Organic Food Industry,? empirically examines how different SBCO forms influence variation and evolution in the content of industry law. This approach moves beyond extant dichotomous conceptualizations of regulation that dominate institutional analyses of regulatory structure. The results of this paper provide answers to questions of when and under what conditions private governance organizations influence variation and evolution of industry regulation.
The third paper, ?Certifying the Harvest: The Role of Standards-Based Certification Organizations in Market Entry and Exit Dynamics,? examines how SBCOs, through key processes of creation of standards, advocacy, verification of compliance, and endorsement, influence patterns of market entry and exit of organic producers. Drawing on state-level and firm-level data sets spanning a 15-year period (1986?2000), I show that SBCOs stimulate entry into the market and that the certification they provide to individual firms inhibits market exit and moderates the competitive effects of increasing form density.Ewing Marion Kauffman Foundation

title: ELECTROSPUN FIBERS FROM BOTH SOLUTION AND MELT: PROCESSING, STRUCTURE AND PROPERTY
abstract: Electrospinning, in which a droplet of polymer liquid is elongated by the action of a strong electrical field, is an effective method to produce submicron scale fibers. The resulting nanofibers are collected as non-woven mats with large surface area to volume ratios which can be used in filtration, catalysis, tissue engineering and reinforced composites. Studies on electrospinning, however, have been limited to relatively simple polymeric systems and researchers have just begun to scratch at the surface of the structure and morphology of various sub-micron scale fibers.

To achieve a fundamental understanding of material-processing-structure relation during nanofiber formation, the following three systems have been investigated experimentally. First, the formation of nanofibers from polylactic acid (PLA) and its nanocomposite solutions has been studied to investigate the effects of inclusion of silica nanoclays. It is observed that the inclusion of nanoclays gives rise to strong cold crystallization, formation of beta crystals and structural orientation in PLA fibers. Electrospun PLA nanocomposite fibers also exhibit improved mechanical properties due to the preservation of intercalated structures and further alignment of nanoclays throughout the entire fiber. We further studied the effect of inclusion of polyethylene oxide (PEO) on PLA fibers. The mechanical properties of PLA are greatly affected by the addition of PEO. Electrospun PLA/PEO blend fibers with less than 10wt% of PEO exhibit increased elongational modulus, yield strength and breaking strain.

Secondly, we have created a unique route to nanofibers directly from the melt which eliminates the organic solvents present in solution electrospinning. This new solvent-free approach not only allows us to investigate a rich array of experimental studies to develop novel nanofibers directly from polymer melts and composites but also opens the door to theoretical routes to model nanofiber formation without the complications associated with solvent evaporation. Sub-micron PLA fibers have successfully been electrospun from its melt by investigating the effects of a series of processing parameters on fiber diameter. The degradation during melt electrospinning has also been studied.

The third system is an extension from melt electrospinning, which is heated solution electrospinning of polyolefin. We explored the possibilities of electrospinning sub-micron polyolefin fibers directly from their solutions and investigated the effects of processing parameters on fiber morphologies and properties.National Science Fundation, Cornell Center for Material Research, Clarcor Inc., DuPont Inc.,

title: Aesthetic Fusions: British Asian Music and Diaspora Culture
abstract: During the mid to late 1990s, popular musicians of South Asian heritage including Nitin Sawhney, Talvin Singh, and State of Bengal were recognized as a significant force in British electronic club music. Music produced within the British Asian diaspora had until then been largely unrecognized within mainstream British culture. The rise of these musicians--often referred to as "Asian Underground"--was new by virtue of their originating largely outside these British Asian communities, and their circulating in British mainstream culture. The recognition of this music within mainstream British culture served to negotiate these musicians' claims to national and cultural belonging. Their claims to British, South Asian, and British Asian identities were defined through a number of factors. Politically, these factors included the history of British colonialism and decolonization in South Asia; immigration and racial politics in Britain; and Britain's recent efforts to reinstate itself as a global economic power. Commercially, these factors included South Asian trends in fashion; the marketing of British Asian musicians in association with the category of "world music"; and their participation in prominent music award ceremonies. Aesthetically, these factors included these musicians' fusing of particular styles, genres, and cultural traditions from South Asia as well as their integration of then cutting-edge trends in electronica music and digital music production. The confluence of these factors coupled with these musicians' physical location in Britain resulted in these musicians' inability to be situated within an established tradition-modernity binary--through which "tradition" has been associated with South Asian culture, and modernity with British or Western culture. Furthermore, these musicians' relation to that binary reveals their participation in a longer history of discourse surrounding British Asian diasporic musicians that questions the chronology and location of globalization as it is conventionally understood. I identify the Indian dancer Uday Shankar as constructing an archetype for the contemporary British Asian diasporic musician as early as the 1920s. Lastly, I specify how this discourse affects how people listen to and

comprehend the music produced by British Asian popular musicians, as well as these musicians' cultural and and political identities.

title: Generalized Preferential Flow Model Validation Using Field-Scale Data
abstract: The challenge in predicting the movement of pesticides and other solutes in soil that exhibits preferential flow conditions is due to the variability in solute velocity through different flow paths. The generalized preferential flow model (GPFM) is a closed form solution to the convective dispersive equation, which combines these different flow paths into multiple groups (i.e. pore groups) with varying properties. The properties that vary between pore groups are limited to the solute velocity, dispersion coefficient, and the contribution to the solute transport. By using the GPFM to predict the solute transport in each pore group, it is possible to obtain an average concentration at any point in the soil profile. However, the GPFM lacks significant field-scale validation.
In order to examine the viability of the GPFM, the predicted results of the model were compared to measured field-scale data. The measured data used to validate the GPFM was from field scale experiments by Gish et al. (2004) and Kung et al. (2000b and 2005). The experiments used conservative tracers, applied at the soil surface, and collected in the discharge of an underground drainage tile. One of these experiments took place at the Walworth County Farm in Elkhorn, Wisconsin and was a long duration, steady state experiment that revealed nearly the entire solute breakthrough at different irrigation rates. The other experiment was conducted at the South East Purdue Agricultural Center (SEPAC) in Butlerville, Indiana and was a short duration, transient flow situation in which tracers were sequentially applied during one experiment.
In order to compare the results of the GPFM with the measured data, modifications were made to the model output to achieve a similar unit to that of the measured data. While modeling the transient flow experiments, other modifications were found to be necessary in order to model a transient process using steady state pieces. The modeling results from the steady state experiment show similar mass recovery rates with differences from the measured data of not more than 5% when the measured results were not affected by external circumstances. The transient flow results were significantly influenced by the water hydrograph for the system but were able to capture the trend of the solute leaching. These results show potential for further implementation of the model. The next step to be addressed is how to measure or systematically specify the modeling parameters.

title: Empirical Analyses of Job Displacements and Productivity
abstract: Committee Chairperson: John Abowd; Other Committee Members: George Jakubson and Kosali Simon.The first chapter of this dissertation integrates the existing literatures on displacement and health by examining the enduring effects of job dislocations that are induced by employment shocks. A joint estimation of hourly wage rates and weekly hours illuminates the disparities in these economic outcomes that exist between those who have reestablished themselves in the workplace subsequent to a layoff and those who have returned to work following the onset of a disability relative to those with uninterrupted job histories. As an extension of these ideas, employment transitions and workplace adjustments are modeled to capture spousal reactions to these shocks. Multiple indicators of health from the Survey of Income and Program Participation and Social Security Administrative benefits records are incorporated into the analyses of those with impairments that prompted job loss. These measures allow knowledge to be gleaned regarding the qualitative differences in the lasting impacts of job cessation resulting from medically diagnosed illnesses as compared to estimates uncovered using survey data sources alone. By considering time durations following these periods of separation in light of these indicators of well-being, a more comprehensive understanding of the long-run repercussions of employee-employer separation is acquired.
The second and third chapters, representing joint work with John M. Abowd and Kevin L. McKinney, address the research and data work that is part of a larger Bureau of Labor Statistics and Bureau of the Census project. We examine the manner in which changes in the composition of the labor force impact productivity by exploiting measures of human capital, or skill. The BLS has previously employed a multifactor productivity to explore changes in the index of labor composition using categories within industry division and year by education, work experience, and gender. We choose to use the centiles of the nationally-weighted human capital distribution from the estimation of a wage equation that includes both person and firm fixed effects to partition the sample of workers into more refined cells. The knowledge of the estimated density function of human capital for each sector enables us to characterize how differences in labor force composition affect labor quality within and between industry divisions over time.

title: SILVER ON SILICON (111): SURFACE STRUCTURAL TRANSFORMATIONS AND TRACE CONTAMINANT EFFECTS AT SUBMONOLAYER COVERAGE
abstract: Committee Chairman: Professor J.M. Blakely; Committee Members: Professor B.W. Batterman, Professor S.L. Sass, Professor J.D. Brock, Professor H.H. Johnson.The structural details for the formation of the (SQRT(3)xSQRT(3))R30deg Silver on Silicon (111) system have eluded definitive resolution for 40 years. Wildly conflicting evidence, gathered by every available surface science technique and theoretical method, is beyond the scale customary for this field. In order for this system to progress, a comprehensive review of the state-of-the-field, a newly constructed surface structure diagram, a new set of experimentally determined atomic positions and the quantitative effects minor contaminants are presented for Ag/Si(111). From careful data mining and analysis of the nearly 600 papers in the literature database, a comprehensive Ag-(SQRT(3)x SQRT(3))R30deg/Si(111) surface structure diagram has been constructed. It includes a new beta-(SQRT(3) xSQRT(3))R30deg phase; a two atom per unit cell proto-cluster variation of the SAV structure, and also a gamma-(SQRT(3)xSQRT(3))R30deg phase; with structure similar to a later variant of the HCT model.
Atomic positions for Ag in the (SQRT(3)xSQRT(3))R30deg and the (3x1) structural conformations have been determined by a number of complementary techniques; X-ray Standing Wave (XSW), Surface Extended X-ray Absorption Fine Structure (SEXAFS), Auger Electron Spectroscopy (AES), Rutherford Backscattering Spectroscopy (RBS), Low Energy Electron Diffraction (LEED) and Isothermal Desorption Spectroscopy (ITDS).
Three second order influences were also evaluated; boron, surface steps and carbon. It was found that boron contamination and low surface steps densities have insignificant influences on the SQRT(3) or (3x1) structures. Minor carbon contamination, however, caused dramatic effects. First, tenth ML levels of carbon completely inhibit the formation of the Ag-(3x1)/Si(111) phase. Second, at low C contamination levels, the Ag-(SQRT(3) xSQRT(3))R30deg layer is comprised of dual, Ag-Si bond lengths (2.2 Angstrom and 2.6 Angstrom); Ag-Ag bond lengths of 3.2 Angstrom; and Ag locations 0.97 Angstrom below the extension of bulk Si(111) planes inferring a Si surface contraction of 0.2 Angstrom. Finally, carbon promoted a high degree of Ag surface order and surface relaxation.
The existence of the beta-(SQRT(3)xSQRT(3))R30deg and gamma-(SQRT(3)x SQRT(3))R30deg phases is fully consistent with quantitative literature citations and helps explain the decades-long debate over model and critical coverage inconsistencies. The profound influence of C, a ubiquitous contaminant in even the best experimental systems, helps explain surface position, relaxation and coverage discrepancies.1) Experiment: National Science Foundation MRL Central Facilities Award No. DMR-9121654.

abstract: Latent Figure Protocol will utilize DNA sequencing technologies to create representational images in which there is a tension between that which is portrayed and the DNA materials (from the specific individual or specific species) used to generate it. Not simply images of a sequence of DNA in a gel (like a standard DNA fingerprint), but rather a gel containing DNA sequences specifically chosen to create a recognizable, quasi-photographic representation. For instance, using a 16-lane electrophoresis gel, it is possible to generate an iconic image by treating each lane as a row of pixels analogous to how early computer images were built using ascii characters. Inserting DNA of known sizes into the beginning slot of each lane will allow for a

sequence of DNA bands in each lane to migrate at different speeds when voltage is applied, thus creating a 2-dimensional grid of DNA bands resembling a low resolution bitmap image.

title: Shoot Positioning Native American (Concord-type) Grapevines
abstract: There has been research on machine shoot positioning at Cornell's Vineyard Laboratory in Fredonia, NY since 1979. Progress has been difficult, but recent developments have resulted in a mechanical shoot positioning system which many growers find satisfactory. This fact sheet is designed to answer questions that have been asked about hand and mechanical shoot positioning. The system is still under development; growers should consulttheir Cornell Cooperative Extension grape extension specialist for recent developments.

title: THE LIMITS OF THE NATIONAL INNOVATION SYSTEMS MODEL: THE CASE OF TURKEY
abstract: The rise of the Neo-Schumpeterian economic thought in the economic development theories in the last two decades put the National Innovation Systems (NIS) approach to the agenda of developing countries. However, a proper consideration should be placed on the external and internal factors that affect the any given country?s capacity in adapting the proposed innovation policies. Thus, the formal innovation systems approach should be incorporated more directly with the studies on the social dimensions of the transition to new knowledge society without being trapped into technological determinism of the Neo-Schumpeterian approach.

title: 'Northern Lights' Apple
abstract: 'Northern Lights' is a new apple variety that ripens in early mid-season (mid-September). It is large and 60 to 100 per cent of its skin is a glossy, attractive bright red. Its flavor is slightly tart, fruity-flavored and very good. In addition to bearing very good fruit, the tree is especially resistant to severely cold winter temperatures. In North Dakota where trees of the very hardy variety, 'Mclntosh,' are often winter injured,

'Northern Lights' trees generally suffer less injury. 'Northern Lights' probably will be most useful for home orchards in severely cold regions near the northern limits of apple growing.

title: ECOTONE PROPERTIES AND INFLUENCES ON FISH DISTRIBUTIONS ALONG HABITAT GRADIENTS OF COMPLEX AQUATIC SYSTEMS
abstract: Ecotone properties (formation and function) were studied in complex aquatic systems in New York State. Ecotone formations were detected on two embayment-stream gradients associated with Lake Ontario during June?August 2002, using abrupt changes in habitat variables and fish species compositions. The study was repeated at a finer scale along the second gradient during June?August 2004. Abrupt changes in

the habitat variables (water depth, current velocity, substrates, and covers) and peak species turnover rate showed strong congruence at the same location on one gradient. The repeated study on the second gradient in the summer of 2004 confirmed the same ecotone orientation as that detected in the summer of 2002 and revealed the ecotone width covering the lentic-lotic transitions. The ecotone on the second gradient acted as a hard barrier for most of the fish species. Ecotone properties were determined along the Hudson River estuary gradient during 1974?2001 using the same methods employed in the freshwater system. The Hudson ecotones showed both changes in location and structural formation over time. Influences of tide, freshwater flow, salinity, dissolved oxygen, and water temperature tended to govern ecotone properties. One ecotone detected in the lower-middle gradient portion appeared to be the optimal zone for fish assemblages, but the other ecotones acted as barriers for most fish species.

A spatially explicit abundance exchange model (AEM) was developed to predict distribution patterns of five fish species in relation to their population characteristics and habitat preferences across the lentic-lotic ecotones on the two freshwater gradients associated with Lake Ontario. Preference indexes of each target fish species for water depth, water temperature, current velocity, cover types, and bottom substrates were estimated from field observations, and these were used to compute fish habitat preference (HP). Fish HP was a key variable in the AEM to quantify abundance exchange of an associated fish species among habitats on each study gradient. The AEM efficiently determined local distribution ranges of the fish species on one gradient. Results from the model validation showed that the AEM was able to quantify most of the fish species distributions on the second gradient.-The Royal Thai Government

title: SYMMETRICAL 1,3-DIGLYCERIDES AS SOLID LIPID MICROPARTICLES FOR CONTROLLED DRUG DELIVERY
abstract: Solid lipid microparticles (SLM) made from triglycerides and waxes are promising colloidal systems for controlled drug delivery. In this study, new symmetrical 1,3-diglycerides compromised of dihydroxyacetone and lipids of varying chain length were synthesized and used to fabricate solid lipid microparticles via a modified solvent-emulsification evaporation method. Particles were physically characterized in terms of size, surface morphology, surface charge as a function of lipid chain length. Scanning electron micrograph images showed that lipid particles display a distinct surface morphology depending on lipid chain length, with morphology transitions from smooth to porous structures with increasing chain length. Results of zeta potential measurements showed that the spheres are negatively charged and are susceptible to Schiff base reaction or reductive amination reaction with primary and secondary amines such as linear- polyethylenimine on the surface. Hydrophobic (nile red) and hydrophilic (rhodamine-B) model drug compounds were incorporated into the microparticles to determine encapsulation efficiency and in vitro release kinetics. Release kinetics of the hydrophobic compound nile red showed increasing release kinetics with increasing chain length, while microparticles incorporating the hydrophilic compound rhodamine-B exhibited burst release characteristics in all cases. These results outline the initial characterization of dihydroxyacetone-based symmetrical 1,3-diglycerides as new materials for controlled drug delivery.

title: Flight periods of the larger species of Moths (macrolepidoptera) that occur in Wstern New York
abstract: This is the second and final report on this project. The first one, published in 1981 (1), was limited to recording the results obtained on 45 members of the family Noctuidae whose larvae feed on vegetable and field crops. Summary information is reported here on all of the 676 members of the Macrolepidoptera collected. The flight period(s) of each species of our study group was determined through the use of electric light traps. These were visited daily from mid-April to mid-November and the moths trapped in them were collected alive into HCN killing jars and taken to the laboratory for sorting out to species. Initially we did not know, or were uncertain about the identity of some species collected; but eventually, we took samples of these to Dr. Franclemont for naming.

title: Risk Assessment of Grape Berry Moth and Guidelines for Management of the Eastern Grape Leafhopper
abstract: Several factors have prompted the reevaluation of control recommendations for key pests of grapes in recent years. First, the costs of insecticides and their application have risen substantially. Growers who improve the efficiency of their use of pesticides can realize significant savings in production costs. Second, grape processors have responded to consumer desires to minimize pesticide residues in food by promoting judicious use of pesticides. Finally, increased governmental restrictions regarding what pesticides can be used in vineyards and how they may be used may increase the overall difficulty that growers encounter when using pesticides. The result of these factors is that while producers and processors continue to require control of economically-damaging pests, this now must be achieved with the least amount of pesticide possible. The Grape Berry Moth Risk Assessment Program was developed to address these concerns. In this publication we describe how Risk Assessment can be used to maintain acceptable control of grape berry moth and the Eastern grape leafhopper while minimizing use of insecticides.

title: A Method to Measure the Environmental Impact of Pesticides
abstract: The purpose of this bulletin is to organize the published environmental impact information of pesticides into a usable form to help growers and other IPM practitioners make more environmentally sound

pesticide choices. This bulletin presents a method to calculate the environmental impact of most common fruit and vegetable pesticides (insecticides, acaricides, fungicides and herbicides) used in commercial agriculture. The values obtained from these calculations can be used to compare different pesticides and pest management programs to ultimately determine which program or pesticide is likely to have the lower environmental impact.

title: Fruit Pest Events and Phenological Development According to Accumulated Heat Units
abstract: Mammals are "warm-blooded" and develop at a constant rate regardless of the environmental temperature, because they are able to maintain an internal temperature that allows their biochemical reactions to progress normally. Insects, which are "exothermic" (the same temperature as their environment; there is no such thing as "cold-blooded"), do not generate body heat, and are therefore limited in their development to periods of favorable external temperature. Below a certain temperature, which varies among species, the insect's biochemical reactions cannot proceed, and development stops. This temperature is known as the insect's developmental threshold ordevelopmental base. By charting the ambient temperature, it is possible to keep track of insect development, which is directly proportional to the amount of time accumulated above the developmental threshold (up to some maximum not often reached during the season). We arbitrarily divide this time into heat units, or degree-days (DD).

title: Sampling Second Generation Spotted Tentiform Leafminer: a Means to Reduce Overall Control Costs and Facilitate Biological Control of Mites in Apple Orchards

abstract: Insecticides commonly used for STLM control (methomyl, oxamyl, and pyrethroids such as esfenvalerate) are highly toxic to predatory mites. Because they greatly reduce mite predator numbers, applications of these insecticides to control STLM often lead to outbreaks of European red mite (Panonychus ulmi) (4,7). In a typical year, however, leafminer populations in most New York orchards do not reach densities high enough to justify insecticidal control. A sampling program that would enable growers to determine the need for controlling STLM would reduce pest control costs by eliminating the need for preventive treatments, and minimizing disruption of naturally occurring biological control of European red mite. This report describes such a sampling program for second generation STLM.

title: Onion Maggot Management in New York, Michigan, and Wisconsin
abstract: The onion maggot (OM) continues to threaten commercial onion production in New York (ca. 12,000 acres), Michigan (ca. 8,000 acres), and Wisconsin (ca. 2,000 acres). In these states, onions are intensively grown on high organic (muck) soils. Because onion production is specialized and costly, many growers concentrate primarily on the one crop, resulting in minimal rotations to other plant species. This practice invariably increases onion maggot pressure, since this insect usually completes three generations per growing season; and has only one major commercial host in the U.S. Immature stages of the OM dwell within or just outside of underground portions of the onion plant. A system where onions are grown either continuously or in close proximity to last year's plantings must rely heavily upon effective soil chemicals applied at seeding to control the larval stages. In addition, sprays are often applied in an attempt to control the adult fly stage. However, sprays directed at flies cannot be relied upon. This is because flies move in and out of onion fields almost continuously. It has been estimated that a single application of short-lived insecticide will contact only a small percentage of the total onion fly population.

title: Small Scale, Sustainable, IPM and Production Systems for Apples in Romania
abstract: Romania, a country in eastern Europe, which is about the size of the state of Wyoming, has a long history of apple production. Production figures during the last several years show that it may be the ninth or tenth largest apple producing country in the world, with about 100,000 hectares of apples. During the last 10 to 20 years, most of the apples from Romania that have been sold outside of local village markets have been produced on large plantings of apples on state-owned farms or cooperatives. Most of the apple planting systems, which were originally adopted from Italian pomologists, are remarkably similar in all of the older

established apple orchards on the state farms throughout the country.

title: 'Fortune' Apple
abstract: 'Fortune' is an excellent dual use variety because it is suitable for fresh and processing markets. 'Fortune' is an apple that gained high praise from growers before being officially named and introduced. In fact, it was so successful in trials throughout the United States that growers strongly requested it be named. The highly colored 'Fortune' is a hybrid of 'Schoharie Spy' x 'Empire' and it combines the desirable attributes of both parents. Itprovides consumers with a large attractive fruit that has good flavor and texture and can be eaten fresh or used in baking or salads. For growers, it offers a mid-season variety that resembles 'Empire' but has the processing characteristics of 'Spy', with less of the production problems of 'Spy'. The slightly spicy flavor is a sprightly blend of sugar and acid. The apple has creamcolor flesh, crisp texture, and stores well.

title: 2005 Rockefeller New Media Foundation Proposal
abstract: The web based project "The Other Americans" will present an electronic poem of the fiercely independent and self-reliant voices that evoke the character of individuals who are living in rural America. The nature of the project is to give voice to the spirit of independence that is alive in communities where the mainstay profession is or used to be that of the family owned farm. I would like to create an archive of voices, moving images, and words that celebrate the spirit of the solitary individual in a world that is increasingly structured, monopolized and corporatised. The community that I have chosen to present is situated in Delaware County, New York. The focus will be on the dairy farmer whose livelihood has been decimated by the advent of giant corporate farms. The web project will weave together a history and memory that will engage the "moment", the "moment" of the "present", the "past" and its "future". It intends to discover the experience of being alive, of living the "everyday", the very poetry that is the act of living. It will present the struggle of individuals who remain true to themselves, their hopes and dreams, in a world that is increasingly dominated by mass culture. The project will emphasize the spirit and humanity of the individual who thinks for himself or herself.

title: Planning Information Infrastructure through a New Library Research Partnership: Interim Report, July 2005
abstract: This document is an interim report on a Small Grant for Exploratory Research (SGER). This interim report was submitted to the National Science Foundation in July 2005.The Cornell Language Acquisition Laboratory and Albert R. Mann Library are in the midst of developing an innovative collaboration between a research laboratory and an academic library to plan for the data preservation and discovery needs of the twenty-first century. Digital technology and internet communication now provide the opportunity to revolutionize the research process, through the ability to store, preserve, share, discover, and reanalyze vast amounts of data. While some disciplines, such as genomics or astronomy, have already developed sophisticated information technology infrastructure for these tasks, others are only beginning such work. In many, if not most research fields, it is especially difficult for those uninitiated to discover where data are located, what they describe, and how they may be used. This project has begun to tackle these issues by taking advantage of the library's existing expertise in preservation, archiving, and metadata creation, building on the existing ontology-software tools the library has developed, and introducing a new conceptual framework that divides the tasks of data sharing into discrete levels that may be managed and presented in defferent ways not only for different audiences but respecting political divisions and control issues that will always be present throughout the laboratories and institutions of academia.This material is based upon work supported by the National Science Foundation, Grant No. 0437603. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

title: The connection between long-term TANF receipt and child maltreatment
abstract: This study provides a clearer understanding of the connections between longterm receipt of TANF (Temporary Aid to Needy Families) benefits, involvement with the child welfare system and child outcomes. Using an ecological model, the study examines the family and community contexts that make it likely for long-term TANF recipients to be involved with the child welfare system. Post-welfare reform state and local

variation in benefit provision have made national comparison difficult. In addition, previous research has not adequately explored whether and how maltreating long-term TANF parents differ from other maltreating parents. The current project was designed to address these gaps in the literature, first, by using a nationally representative sample and secondly, by the use of qualitative interviews focusing on the stressors and life events that may make it more likely for long-term TANF recipient families to be involved with the child welfare system.

The first phase of the study consists of a secondary data analysis using Waves I to 4 of the National Survey of Child and Adolescent Well-Being (NSCAW). NSCAW is the first nationally representative longitudinal survey of children and families involved with the child welfare system. Previous research has examined the involvement of TANF recipient families in the child welfare system. Unlike previous research, this study begins with a child welfare sample and examines the differences between long-term TANF recipient families and non-recipient families in the context of risk, family characteristics and outcomes.

Custodial mothers who were long-term TANF recipients (n = 320, representing a population of 196, 375) were compared to custodial mothers who are not current TANF recipients and who had with less than one year of lifetime receipt of public cash assistance benefits (n = 1401, representing a population of 923, 304). Regression analyses were conducted to determine significant differences in demographics, life experience, risk factors and family and child outcomes. Analyses revealed significant differences between groups at study inception and throughout the 36 months of follow up, with poorer outcomes for children and mothers in the long-term TANF group.

The second phase of the study consists of qualitative interviews of long-term public assistance recipients in upstate New York. Interviews were conducted with 17 subjects who responded to a flier. The qualitative interviews were designed to obtain descriptive information about the life stressors experienced by study participants and the obstacles that they face in negotiating the TANF and child welfare systems. The qualitative interviews supplement the secondary data analysis and provide detail that cannot be derived from the survey responses. The majority of participants had involvement with the child welfare system. Participants presented with a complex set of chronic problems, including mental illness and experience of domestic violence.This research was funded by a 2006 summer fellowship from the Cornell University Department of Human Development, and a master?s research grant from the Cornell University Department of Human Development.

title: Assessing models of outreach in ELSI projects: Final Report to the DOE's ELSI program
abstract: Final Report.This report examined the presence of four models of science communication in outreach projects funded by the U.S. Department of Energy's Ethical, Legal, and Societal Implications (ELSI) program. The four models were: deficit model, contextual model, lay knowledge model, and public engagement model. Although theoretical literature in science communication has recently been highly critical of the deficit model, we found that most projects -- including those that labeled themselves as public engagement -- contained a substantial amount of deficit model communicatioU.S. Department of Energy

abstract: Mu Gu Gai Pan Over Rice Special #8 consists of seven to ten different Chinese folk toys collected

from rural areas of China that are mechanically enhanced and then instructed to chase visitors around an exhibition space. Inspired by China's rapid industrialization and urbanization and effect of this change on rural culture, Mu Gu will respectfully "update" traditional handmade toys with new "features" and "capabilities." Outfitted with electronics and light sensors, the mechanized folk toys are part of an interactive installation that combines high and low technology to create pieces that interact with one another and with the viewer.

title: CROSSTEX: A Description of the Experimental Condtions, Wave Climate, and Inner Surf Zone Hydrodynamics
abstract: Edwin A. Cowen (Todd), Phillip L-F Liu, Charles H. K. WilliamsonThe Cross Shore Sediment Transport Experiments (CROSSTEX) are a group of experiments examining sediment transport processes in the near shore environment with the goal of improving process based models for sediment transport. This is accomplished via large scale lab experiments utilizing advanced instrumentation and controlled, repeatable wave conditions as well as a natural sand beach. One section of these experiments examined sediment transport in the swash zone, the alternating wet and dry portion of the beach. Velocity data was collected from outside the breaker line into the surf zone, along with free surface measurements throughout the tank. Additional instrumentation to measure optical backscatter, sediment grain velocity and water pressure was deployed in the near shore. Waves consisted of regular, 5th order Stokes waves with wave heights ranging from 12 cm to 30 cm, two runs with a simple bi-chromatic wave train and one run with random waves. An analysis of wave climate stability and wave repeatability indicates the wave tank approaches a steady, repeatable wave climate after approximately 5 minutes although bathymetry changes ultimately affect repeatability in the near shore. Comparison of the time averaged mean free surface with empirical estimates shows good agreement with other studies conducted in both the field and wave tanks. Phase averaged velocity profiles taken in the offshore by an Acoustic Doppler Current Profiler (ADCP) indicate a 2-D flow environment with minimal along shore flow and repeatable wave conditions. An alternate processing scheme was developed for the ADCP data to allow redundant estimates of each velocity component which was used to assess flow uniformity. Phase averaged velocity data in the surf zone taken from Acoustic Doppler Velocimeters (ADVs) revealed occasional strong along shore flow and more complex flow structure, but supports wave repeatability. Analysis of the bathymetry data in the surf zone revealed strong along shore gradients, which contribute to the more complex flow seen in the surf zone. Surf zone turbulence obtained by applying a linear predictive filter to velocity signals and differencing the filtered and original signals indicates plunging to weakly plunging breaking conditions as well as providing order of magnitude estimates of turbulent dissipation in the surf zone. Recommendations for the conduct of future large scale experiments (field or lab) in the surf zone and in general, and future work on the present data are provided.National Science Foundation

title: 2005 Rockefeller New Media Foundation Proposal
abstract: "Chapter 3: Object of Desire" is a net artwork created under the larger umbrella of the integrated-media project World of Awe. At the core of World of Awe is a traveler's journal that explores the connections between storytelling, travel, memory and technology in a parallel world that is situated between night and day. "Chapter 3: Object of Desire," focuses on a mythological relationship between an individual and an uncharted landscape. To detach the single voice from a specific cultural identity, it is split into three languages: English, Hebrew and Arabic. Rather than a literal one-to-one translation, these three languages overlap and mix to create a trilingual story space. The project integrates the network into the story by strategically distributing the files to servers in the US, Jordan and Israel. By incorporating this information into the design, visitors will see that their commands are crossing national borders, demonstrating the collapse of geographical locations in a virtual, narrated space. Because of current political events and the influence of media, these three languages are almost always associated with conflict and strife. This project offers an opportunity to create a counter narrative that merges all three languages into a single voice to express some of the most basic concerns of human existence: love, the relationship to one's body, to a landscape, a home, and life and death.

title: 2005 Rockefeller New Media Foundation Proposal
abstract: I propose a collection of conceptually-oriented interactive installations, called the Eye Contact Systems, which explore the questions: what if artworks could know that we were looking at them? And, given this knowledge, what if they could look back at us? The Eye Contact Systems are intended to explore the possibilities of granting interactive artworks with new perceptive capabilities-namely, knowing where we are looking-and new expressive means, namely, simulated mechanical eyes that can look at us. The series of artworks proposed here are made possible by recent advances in gaze-tracking technology. This term refers to a set of computer-vision techniques, wherein a computer fitted with a high-resolution video camera is able to reliably estimate where a subject is looking. Thus, although the individual pieces in the proposed series take a variety of forms (including wall projections, small mechatronic sculptures, and roomlike installations), they share (in addition to their common thematic thread) the common technical infrastructure of a gaze-tracking system. It happens that this infrastructure is difficult to create, while many of the individual artworks proposed here will be relatively simple to build, once the infrastructure is in place. This proposal, therefore, seeks support to develop such a technical infrastructure, as well as the many artworks that it will make possible.

title: STUDIES OF INORGANIC-ORGANIC INTERFACE FORMATION
abstract: Inorganic-organic interfaces are playing a key role in a number of emerging technologies. For instance, formation of a robust interface between organic and inorganic materials will play an important role in the successful fabrication of "molecular electronic" devices. Self-assembly has been successfully used to make the so-called ?bottom contact?. The techniques for ?top contact? formation are still not very well developed. Physical vapor deposition of the top contact metal is the most common approach but it has the disadvantages that it causes penetration and disruption of the organic layer. An alternative strategy has been employed here, where a transition metal coordination complex has been used as the interface initiator. The formation of an interface between tetrakisdimethyl(amido)titanium, Ti[N(CH3)2]4, and conjugated oligo(phenylene-ethynylene) self-assembled monolayers (SAMs) possessing iso-propylamine terminal functional groups on polycrystalline gold was studied. Extent of reaction and stoichiometry at the interface has also been investigated in this study.

In the ever evolving field of semiconductor manufacturing, organic materials are becoming increasingly important. Copper is now the choice for metallization, and there is a drive to incorporate carbon-containing, possibly purely organic, and/or porous low dielectric constant (?) interlayer dielectrics to reduce the capacitive cross talk. The deposition of barrier layers between the Cu and the low-? materials is challenging, particularly for carbon-containing, porous dielectrics. Self-assembled monolayers have been utilized to modify dielectric surfaces in order to activate them for the deposition of a smooth and conformal diffusion barrier. More specifically, the atomic layer deposition (ALD) of titanium nitride (TiN) employing molecular beams of Ti[N(CH3)2]4, and ammonia, NH3 has been investigated. Deposition was achieved on silane SAMs on SiO2 possessing different terminations and chain lengths. Nucleation and growth stages were studied by making use of a variety of metrology and surface analysis techniques, namely: ellipsometry, X-ray photoelectron spectroscopy, Rutherford backscattering spectrometry, atomic force microscopy, and scanning transmission electron microscopy. The nature of the interactions between the SAM terminal group and Ti[N(CH3)2]4 was pivotal in determining the growth pattern. The growth behavior was also investigated on hyperbranched polymeric films on SiO2 as well as porous low ? substrates modified using these polymeric films.

title: 2005 Rockefeller New Media Foundation Proposal
abstract: The Story of Jennifer and Kevin McCoy is an on-going project in which we restage scenes from our lives as they intersect media and culture. The pieces consist of miniature film sets, dozens of live miniature cameras with computerized switches, and video projection. For our fellowship period, we intend to develop site-specific installations as part of this series of works. To date, we have completed stand-alone sculptures using a similar form and one site-specific work that has ignited our interest. This piece is installed at JFK's Terminal 5 and uses the architecture of the space as a backdrop for our miniature scenes. In new site-specific sculptures, we intend to research and develop strategies for the wireless transmission of images across farther distances, enabling the scattering of the fragmentary physical scenarios across larger and more unorthodox exhibition venues. In our proposed project, we will miniaturize narrative fragments, some from our lives and some from fictional scenarios. These parts are crosscut and interwoven to create a highly mediated form of autobiography in which our personal mythologies are made indistinguishable from our experience as spectators of media. Formally, we are interested in the difference between the three dimensional unrealistic space of the models and the realistic simulation the computers and cameras can create. Motors are also used

in this work to further the sense of cinematic illusion.

abstract: I propose an online project in the form of a website that poses questions to its visitors. The answers will create an ongoing narrative that will present the contributions in the order in which these are submitted. The questions will propose minimal contexts which the viewer will be asked to consider as starting points to create their own narratives. The contributions will be accepted for a period of one year. Throughout this period, I will develop animated graphics that will complement the online contributions; these graphics will eventually become the visual foundation for a fiction story that I will write in reaction to the submitted material. Finally, the fiction story and graphics will be adapted into an experimental video that will be available for viewing on the web, as well as in DVD format.

title: 2005 Rockefeller New Media Foundation Proposal
abstract: Art has often been considered an "agent of transformation." However, what happens when the art and the spaces where we present it are in a state of flux and transformation? During the twentieth century, mechanics allowed us to incorporate notions of speed and motion into visual representation. New technologies give us the possibility to create forms in transformation, avoiding the limitations of particularity and singularity. These mutant forms might respond to a public space that is mutating too. Forms can be combined and recombined seamlessly as if we were altering their genetic or molecular composition. The public space has become more public in its virtual representation. Cities exist not just in reality but also in a mythical construction that we inhabit from elsewhere. Through web cams and the Internet we can access certain specific locations without having to be there. Here, radical hypothetical interventions within the public space and certain communities can actually become a reality.

title: Crustal and upper mantle structure of Oman and the Northern Middle East

See also: http://atlas.geo.cornell.edu/oman/publications/Al-Lazki_dissertation.htmThis dissertation focuses on studying the crustal structure on the southeast margin and foreland of Arabia in Oman, and upper mantle rheology and structure at the zone of interaction between the Arabian, Eurasian, and African plates (Figure 1.1). At the center of the study area, the Arabian plate is bounded in the east by the Indian plate along the Owen and Murray Transform Fault zones, in the northeast and north it is bounded by the Eurasian plate along the ZagrosBitlis Suture zones, and in the west, northwest, and southwest it is bounded by the African plate along the Dead Sea Fault, the Red Sea, and the Gulf of Aden (Figure 1.1). Northwest of Arabia, the Hellenic and the Cyprean arcs define the convergence boundary between the African plate and the Anatolian plate in eastern Mediterranean Sea (Figure 1.1).

One of the most important events throughout geologic history of the region is the closure of the NeoTethys ocean. It began in Early Cretaceous along the eastern and northeastern boundaries of the Arabian-Africa Plate and lasted to Pliocene times (Sengor and Yilmaz, 1981). Ophiolite emplacement is a process that commonly accompanied the closure and subduction of the NeoTethys ocean. At present day a belt of NeoTethyan ophiolites follows the suture zone between the Arabian-Eurasian plate boundary and farther west within the Anatolian plate (Figure 1.1). While at the north and northeast boundaries of the Arabian plate the closure of the NeoTethys and final suturing processes have concluded and resulted in the building of the Iranian-Anaoltian plateaus, at the southeast Arabian plate boundary, a piece of the NeoTethys oceanic lithosphere (Semail Ophiolites) was emplaced in the late Cretaceous, but the closure process is still ongoing by subducting the remnant basin of Oman at the Makran Subduction zone (Figure 1.1).

At a later stage, the opening of the Red Sea and Gulf of Aden is thought to have occurred episodically (Hempton, 1987). An initial phase occurring in the period Middle-Late Eocene and a later phase occurred in the Early Pliocene (~14.5 Ma) (Hempton, 1987). This separation of Arabia from Africa accommodated by the left lateral Dead Sea Fault System is thought to be responsible for the reorganization of relative plate motions in the Anatolian Plateau (Eurasian plate) (Sengor and Yilmaz, 1981). In early Pliocene, continued N-S convergence between Arabia and Eurasia resulted in the extrusion of an Anatolian plate along the North Anatolian Fault (NAF) and the East Anatolian Fault (EAF) zones (Bozkurt, 2001). The Anatolian plate's westward escape is converging along the Hellenic and Cyprean subduction zones, where Africa's oceanic

lithosphere is being subducted.

Chapter two of this dissertation presents a detailed study of the crustal structure along 255 km long transect that includes the hinterland, the mountains, and the foreland of Oman. The main objective of this study is to investigate the crustalscale structure of the eastern Arabian margin, across the 3,000 meters high Oman Mountains. Various geophysical and geological data are used to model the crustal thickness along the transect. We used exploration seismic and well data to constrain the upper 78 km of the sedimentary column, receiver function to infer Moho depth along the transect, and gravity modeling to constrain Moho lateral variations and infer a basement depths along the transect. Furthermore, integrated geological and geophysical data shed valuable information about the processes that accompanied the Semail Ophiolite emplacement.

Chapter three focuses on the young continent-continent collision zone between northern Arabia and Eurasia along the Bitlis-Zagros Suture zone. We use Pn tomography to further our knowledge about the mantle lithosphere rheology and structure and its contribution to lithosphere dynamics at the young Bitlis-Zagros continent-continent collision zone. Pn velocities higher than 8 km/s are used to infer stable mantle lid, while Pn velocities less than 8 km/s are used to infer mantle lid instability. Chapter four presents evidence on upper mantle rheology using Pn velocity and structure and using Pn anisotropy at the junction of the Arabian, Eurasian, and African plates. This research looks at the larger scale picture of the three plates' interactions and use Pn velocity and anisotropy to contrast regions underlain by stable mantle lid from those unstable and to investigate uppermost mantle processes. This study, also, focuses on regions underlain by small scale (< 200 km) very low Pn velocity anomalies that indicate thinned to absent mantle lid. This study compares Pn velocity with Sn attenuation map of the region. It also compares observed Pn azimuthal anisotropy with shear wave SKS polarization anisotropy to infer asthenospheric mantle deformation.

title: Crustal structure of the Arabian Plate: New constraints from the analysis of teleseismic receiver functions
abstract: An edited version of this paper was published by Elsevier Science. Copyright 2005, Elsevier Science. See also: http://dx.doi.org/10.1016/j.epsl.2004.12.020; http://atlas.geo.cornell.edu/SaudiArabia/publications/Al-Damegh%202005.htmReceiver functions for numerous teleseismic earthquakes recorded at 23 broadband and mid-band stations in Saudi Arabia and Jordan were analyzed to map crustal thickness within and around the Arabian plate. We used spectral division as well as time domain deconvolution to compute the individual receiver functions and receiver function stacks. The receiver functions were then stacked using the slant stacking approach to estimate Moho depths and Vp/Vs for each station. The errors in the slant stacking were estimated using a bootstrap re-sampling technique. We also employed a grid search waveform modeling technique to estimate the crustal velocity structure for seven stations. A jackknife re-sampling approach was used to estimate errors in the grid search results for three stations. In addition to our results, we have also included published receiver function results from two temporary networks in the Arabian shield and Oman as well as three permanent GSN stations in the region.

The average crustal thickness of the late Proterozoic Arabian shield is 39 km. The crust thins to about 23 km

along the Red Sea coast and to about 25 km along the margin of the Gulf of Aqaba. In the northern part of the Arabian platform, the crust varies from 33 to 37 km thick. However, the crust is thicker (41?53 km) in the southeastern part of the platform. There is a dramatic change in crustal thickness between the topographic escarpment of the Arabian shield and the shorelines of the Red Sea. We compared our results in the Arabian shield to nine other Proterozoic and Archean shields that include reasonably well determined Moho depths, mostly based on receiver functions. The average crustal thickness for all shields is 39 km, while the average for Proterozoic shields is 40 km, and the average for Archean shields is 38 km. We found the crustal thickness of Proterozoic shields to vary between 33 and 44 km, while Archean shields vary between 32 and 47 km. Overall, we do not observe a significant difference between Proterozoic and Archean crustal thickness.

We observed a dramatic change in crustal thickness along the Red Sea margin that occurs over a very short distance. We projected our results over a cross-section extending from the Red Sea ridge to the shield escarpment and contrasted it with a typical Atlantic margin. The transition from oceanic to continental crust of the Red Sea margin occurs over a distance of about 250 km, while the transition along a typical portion of the western Atlantic margin occurs at a distance of about 450 km. This important new observation highlights the abruptness of the breakup of Arabia. We argue that a preexisting zone of weakness coupled with anomalously hot upper mantle could have initiated and expedited the breakup.

title: Lithospheric Structure of the Arabian Plate and Surrounding Regions
abstract: Copyright 2003, Khaled Al-Damegh See also: http://atlas.geo.cornell.edu/SaudiArabia/publications/Al-Damegh%20Dissertation%202004.htmContinuous waveform recording from a newly established broadband seismic network in Saudi Arabia, in addition to data produced by other stations in the region, were used to map regional seismic wave propagation (Lg and Sn) and Pn attenuation. Moreover, crustal thickness in the Arabian plate was also estimated based on receiver function analysis.

Zone blockage and inefficient Sn propagation is observed along and to the east of the Dead Sea fault system and in the northern portion of the Arabian plate (south of the Bitlis suture)., We observed Sn blockage across some segments of the Red Sea. These regions of high Sn attenuation have anomalously hot and possibly thin lithospheric mantle (i.e., mantle lid). Consistent with our Sn attenuation findings, we also observed low Qpn along the western portion of the Arabian plate and along the Dead Sea fault system. Our results imply the presence of a major anomalously hot and thinned lithosphere in these regions that may be caused by the extensive upper mantle anomaly that appears to span most of east Africa and western Arabia. These mapped zones of high attenuation closely coincide with an extensive Neogene and Quaternary volcanic activity.

We found that the average crustal thickness of the Arabian shield is 39 km. The crust thins to about 23 km along the Red Sea coast and to about 25 km along the Gulf of Aqaba. We observed a dramatic change in crustal thickness between the topographic escarpment of the Arabian shield and the shorelines of the Red Sea. We compared our results in the Arabian shield to nine other Proterozoic and Archean shields that include reasonably well-determined Moho depths. We do not observe a significant difference between Proterozoic and Archean crustal thickness. Our observations show that the transition from oceanic to continental crust along the Red Sea margin occurs over a relatively short distance compared to a typical west Atlantic continental margin.

We argue that the anomalous nature of the Red Sea margin may be one of the consequences of the presence of a mega plume that extends from the core-mantle boundary into the upper mantle beneath east Africa, the Red Sea, and the western portion of the Arabian plate. In addition, the site where the sea-floor spreading of the Red Sea occurred was a Proterozoic suture and a zone of weakness. These observations combined may explain the relatively abrupt breakup of the Arabian plate and the anomalous nature of the Red Sea margin.

title: Regional seismic wave propagation (Lg and Sn) and Pn attenuation in the Arabian Plate and surrounding regions
abstract: An edited version of this paper was published by Blackwell Publishing. Copyright 2004, Blackwell Publishing.

See also:
http://www.blackwell-synergy.com/doi/abs/10.1111/j.1365-246X.2004.02246.x; http://atlas.geo.cornell.edu/MiddleEastNorthAfrica/publications/Al-Damegh2004.htmContinuous recordings of 17 broadband and short period digital seismic stations from a newly established seismological network in Saudi Arabia, along with digital recordings from the broadband stations of the GSN, MEDNET, GEOFON, a temporary array in Saudi Arabia, and a temporary short period stations in Oman, were analyzed to study the lithospheric structure of the Arabian plate and surrounding regions. The Arabian plate is surrounded by a variety of types

of plate boundaries: continental collision (Zagros belt and Bitlis suture), continental transform (Dead Sea fault system), young sea floor spreading (Red Sea and Gulf of Aden), and oceanic transform (Owen fracture zone). Also, there are many intraplate Cenozoic processes such as volcanic eruptions, faulting, and folding that are taking place.

We used this massive waveform database of more than 6200 regional seismogram to map zones of blockage, inefficient, and efficient propagation of the Lg and Sn phases in the Middle East and East Africa. We observed Lg blockage across the Bitlis suture and Zagros fold and thrust belt, corresponding to the boundary between the Arabian and Eurasian plates. This is probably due to a major lateral change in the Lg crustal wave-guide. We also observed inefficient Lg propagation along the Oman mountains. Blockage and inefficient Sn propagation is observed along and for a considerable distance to the east of the Dead Sea fault system and in the northern portion of the Arabian plate (south of the Bitlis suture). These mapped zones of high Sn attenuation, moreover, closely coincide with extensive Neogene and Quaternary volcanic activity. We have also carefully mapped the boundaries of the Sn blockage within the Turkish and Iranian plateaus. Furthermore, we observed Sn blockage across the Owen fracture zone and across some segments of the Red Sea. These regions of high Sn attenuation most probably have anomalously hot and possibly thin lithospheric mantle (i.e., mantle lid). A surprising result is the efficient propagation of Sn across a segment of the Red Sea; an indication that active sea floor spreading is not continuous along the axis of the Red Sea. We also investigated the attenuation of Pn phase (QPn) for 1-2 Hz along the Red Sea, Dead Sea fault system, within the Arabian shield, and in the Arabian platform. Consistent with the Sn attenuation, we observed low QPn values of 22 and 15 along the western coast of the Arabian plate and along the Dead Sea fault system, respectively, for a frequency of 1.5 Hz. Higher QPn values on the order of 400 were observed within the Arabian shield and platform for the same frequency. Our results based on Sn and Pn observations along the western and northern portions of the Arabian plate imply the presence of a major anomalously hot and thinned lithosphere in these regions that may be caused by the extensive upper mantle anomaly that appears to span most of east Africa and western Arabia.

title: Pn tomographic imaging of mantle lid velocity and anisotropy at the junction of the Arabian, Eurasian, and African plates
abstract: An edited version of this paper was published by Blackwell Publishing in Geophysical Journal International. Copyright 2004, Blackwell Publishing. See also: http://www.blackwell-synergy.com/doi/abs/10.1111/j.1365-246X.2004.02355.x; http://atlas.geo.cornell.edu/MiddleEastNorthAfrica/publications/Al-Lazki2004.htmThe interaction of the Arabian plate with the Eurasian plate has played a major role in building the young mountain belts along the Zagros-Bitlis continent-continent collision zone. Arabia's northward motion is considered to be the primary driving force behind the present-day westerly escape of the Anatolian plate along the North and East Anatolian fault zones as well as the formation of the Turkish and the Iranian plateaux. In this study we mapped Pn-wave velocity and anisotropy structures at the junction of the Arabian, Eurasian and African plates in order to elucidate the upper-mantle dynamics in this region. Pn is a wave that propagates within the mantle lid of the lithosphere and is often used to infer the rheology and fabric of the mantle lithosphere. Applying strict selection criteria, we used arrival times of 166 000 Pn phases to invert for velocity and anisotropy in the region. Using a least-squares tomographic code, these data were analyzed to solve simultaneously for both velocity and azimuthal anisotropy in the mantle lithosphere.

We found that most of the continental regions in our study area are underlain by low Pn velocity structures. Broad-scale (~500 km) zones of low (<8 km s-1) Pn velocity anomalies underlie the Anatolian plate, the Anatolian plateau, the Caucasus region, northwestern Iran and northwestern Arabia, and smaller scale (~200

km), very low (<7.8 km s-1) Pn velocity zones underlie southern Syria, the Lesser Caucasus, the Isparta Angle, central Turkey and the northern Aegean Sea. The broad-scale low-velocity regions are interpreted to be hot and unstable mantle lid zones, whereas very low Pn velocity zones are interpreted to be regions of no mantle lid. The low and very low Pn velocity zones in eastern Turkey, northwestern Iran and the Caucasus region may be associated with the latest stage of intense volcanism that has been active since the Late Miocene. The low Pn velocity zones beneath the Anatolian plate, eastern Turkey and northwestern Iran may in part be a result of the subducted Tethyan oceanic lithosphere beneath Eurasia. We also found a major low-velocity zone beneath northwestern Arabia and the Dead Sea fault system. We interpret this anomaly to be a possible extension of the hot and anomalous upper mantle of the Red Sea and East Africa rift system. High Pn velocities (8.1-8.4 km s-1) are observed to underlie the Mediterranean Sea, the Black Sea, the Caspian Sea, and the central and eastern Arabian plate. Observed Pn anisotropy showed a higher degree of lateral variation than did the Pn velocity structure. Although the Pn anisotropy varies even in a given tectonic region, in eastern Anatolia very low Pn velocity and Pn anisotropy structures appear to be coherent.

title: Geophysical and geological databases and CTBT monitoring: A case study of the Middle East
abstract: Copyright 1996, Kluwer Academic Publishers. See also: http://atlas.geo.cornell.edu/MiddleEastNorthAfrica/publications/Barazangi1996.htmWith the anticipated completion of multilateral comprehensive nuclear test ban and nonproliferation treaties in the near future, it is essential for the monitoring efforts that multidisciplinary information on a given region is readily available and accessible in a digital, on-line format via electronic networks for use by concerned researchers and decision makers.

We are collecting and organizing all available seismological, geophysical, topographical, geological, and satellite imagery datasets for the Middle East and North Africa into a digital information system that is quickly accessible via the Internet from Cornell and can be utilized in modeling and display programs. We are focusing recent efforts on the Middle East and North Africa to complement our previous work in Europe and Central Asia. We are locating and digitizing published crustal thickness, depth to basement, and crustal velocity and density structures, primarily as interpreted from seismic refraction and reflection, gravity and drill hole datasets. We have also digitized some gravity maps and key geologic features for the Middle East. All data are being stored in Arc/Info Geographic Information System (GIS), the most widely used full-featured GIs We are also maintaining a comprehensive bibliography of all the relevant references in a computer database.

The results of ongoing efforts are essential for a successful global monitoring system, such as the one tested by the GSETT-3 experiment. These results, for example, will significantly contribute to accurate locations of seismic events, understanding high-frequency wave propagation at regional distances, and better characterization and calibration of seismic events in the region.

title: Tomographic imaging of Lg and Sn Propagation in the Middle East
abstract: An edited version of this paper was published by Springer Verlag. Copyright 2001, Springer Verlag. See also: http://www.springerlink.com/content/kha0p6rdaqhbqckq/; http://atlas.geo.cornell.edu/MiddleEastNorthAfrica/publications/Sandvol2001.htmObservations based on relatively limited data recorded

by sparsely distributed stations have indicated that regional seismic phase propagation (Lg and Sn) is very complex in the Middle East. Accurate characterization of regional seismic wave propagation in this region necessitates the use of a large number of seismic stations. We have compiled a large data set of regional and local seismograms recorded in the Middle East. This data set comprises approximately four years of data from national short-period networks in Turkey and Syria, data from temporary broad band arrays in Saudi Arabia and the Caspian Sea region, and data from GSN, MEDNET, and GEOFON stations in the Middle East. We have used this data set to decipher the character and pattern of regional seismic wave propagation. We have mapped zones of blockage as well as inefficient and efficient propagation for Lg, Pg, and Sn throughout the Middle East. Two tomographic techniques have been developed in order to objectively determine regions of lithospheric attenuation in the Middle East.

We observe evidence of major increase in Lg attenuation, relative to Pg, across the Bitlis suture and the Zagros fold and thrust belt, corresponding to the boundary between the Arabian and Eurasian plates. We also observe a zone of inefficient Sn propagation along the Dead Sea fault system which coincides with low Pn velocities along most of the Dead Sea fault system and with previous observations of poor Sn propagation in western Jordan. Our observations indicate that in the northern portion of the Arabian plate (south of the Bitlis suture) there is also a zone of inefficient Sn propagation that would not have been predicted from prior measurements of relatively low Pn velocities. Mapped high attenuation of Sn correlates well with regions of Cenozoic and Holocene basaltic volcanism. These regions of uppermost mantle shear-wave attenuation most probably have anomalously hot and possibly thin lithosphere.

title: Grid search modeling of receiver functions: Implications for crustal structure in the Middle East and North Africa
abstract: An edited version of this paper was published by the American Geophysical Union (AGU). Copyright 1998, AGU. See also: http://www.agu.org/pubs/crossref/1996/95JB03112.shtml; http://atlas.geo.cornell.edu/MiddleEastNorthAfrica/publications/Sandvol1998.htmA grid search is used to estimate average crustal thickness and shear wave velocity structure beneath 12 three-component broadband seismic stations in the Middle East, North Africa, and nearby regions. The crustal thickness in these regions is found to vary from a minimum of 8.0 +/- 1.5 km in East Africa (Afar) region to possibly a maximum of 64 +/- 4.8 km in the lesser Caucasus. Stations located within the stable African platform indicate a crustal thickness of about 40 km. Teleseismic three-component waveform data produced by 165 earthquakes are used to create receiver function stacks for each station. Using a grid search, we have solved for the optimal and most simple shear velocity models beneath all 12 stations. Unlike other techniques (linearized least squares or forward modeling), the grid search methodology guarantees that we solve for the global minimum within our defined model parameter space. Using the grid search, we also qualitatively estimate the least number of layers required to model the observed receiver functions' major seismic phases (e.g., PSMoho). A jackknife error estimation method is used to test the stability of our receiver function inversions for all 12 stations in the region that had recorded a sufficient number of high-quality broadband teleseismic waveforms. Five of the 12 estimates of crustal thickness are consistent with what is known of crustal structure from prior geophysical work. Furthermore, the remaining seven estimates of crustal structure are in regions for which previously there were few or no data about crustal thickness.

title: Crustal model for the Middle East and North Africa region: Implications for the isostatic compensation mechanism
abstract: An edited version of this paper was published by Blackwell Publishing. Copyright 2001, Blackwell Publishing. See also: http://www.blackwell-synergy.com/doi/abs/10.1111/j.1365-246X.2004.02246.x; http://atlas.geo.cornell.edu/MiddleEastNorthAfrica/publications/Seber2001.htmWe present a new 3-D crustal model for the Middle East and North Africa region that includes detailed topography, sediment thickness, and Moho depth values. The model is obtained by collecting, integrating, and interpolating reliable, published sedimentary rock thickness and Moho depth measurements in the Middle East and North Africa region. To evaluate the accuracy of the model, the 3-D gravity response of the model is calculated and compared with available observed Bouguer gravity anomalies in the region. The gravity modelling shows that the new crustal model predicts large portions of the observed Bouguer anomalies. However, in some regions, such as the Red Sea and Caspian Sea regions, where crustal structure is relatively well-determined, the residual anomalies are of the order of a few hundred milligals. Since the new crustal model results in large residual anomalies in regions where reasonably good constraints exist for the model, these large residuals cannot simply be explained by inaccuracies in the model. To analyze the cause of these residuals further we developed an isostatically compensated (Airy-type) Moho-depth model and calculated its gravity response. Isostatic gravity anomalies are in nearly perfect agreement with the observed gravity values. However, the isostatic model differs significantly from the new (3-D) crustal model. If isostasy is to be maintained, crustal and /or upper mantle lateral density variations are needed to explain the large observed gravity residuals.

title: Intracontinental rifting and inversion: Missour Basin and Atlas Mountains, Morocco
abstract: An edited version of this paper was published by the American Association of Petroleum Geologists (AAPG). Copyright 1996, AAPG. See also: http://www.aapg.org/bulletin/index.cfm; http://atlas.geo.cornell.edu/morocco/publications/beauchamp1996.htmThe intracontinental High and Middle Atlas mountain belts in Morocco intersect to form the southern and western margins of the Missour Basin, an intermontane basin formed as a result of the uplift and inversion of the Mesozoic Atlas paleorifts. These rifts were areas where the crust was greatly attenuated and more subject to deformation in response to nearby plate boundary tectonics. Data from observations based on seismic reflection profiles and wells over the Missour basin for hydrocarbon exploration and field mapping were used to understand the basin evolution, structural styles, and inversion timing of the nearby Atlas Mountains. Hercynian and Mesozoic normal faults were reactivated into high-angle reverse and thrust faults in the Mesozoic during the Jurassic, early Cretaceous (early Alpine phase), and the Paleogene (late Alpine phase). The reactivation of synrift normal faults of the paleo-Atlas rifts inverted previous half grabens into anticlinal structures, with the axis of the half graben centered below the axis of the inverted anticline. The resulting inverted fold geometries are controlled by the geometries of the extensional planar or listric faults.

title: Inversion tectonics and the evolution of the High Atlas Mountains, Morocco, based on a geological-geophysical transect
abstract: An edited version of this paper was published by the American Geophysical Union (AGU). Copyright 1998, AGU. See also: http://www.agu.org/pubs/crossref/1999/1998TC900015.shtml; http://atlas.geo.cornell.edu/morocco/publications/beauchamp1999.htmThe High Atlas Mountains of North Africa were formed over a major intracontinental rift system that had extended from what is now the Atlantic margin of Morocco to the Mediterranean coast of Tunisia. The Atlas rift system began in the Triassic and was active through the Jurassic. The inversion phase of the Atlas rift system began in the Early Cretaceous and extended into the present. The major uplift phase occurred between 30 and 20 Ma (Oligocene-Miocene) and corresponds to the Alpine orogenic event. The uplift and inversion of the Atlas rift system resulted in a shortening of the rift basin by a minimum of 36 km. A restoration of the deformed cross section indicates the original Atlas rift basin was approximately 113 km wide, comparable to the width of the present-day Red Sea. Synrift and postrift sedimentary rocks were uplifted by the reactivation of synrift normal faults, with further shortening along newly formed thin-skinned thrust faults. Structures formed by the reactivation of synrift faults resulted in structures with different geometries than those created by newly formed fault-bend and fault-propagation faults. Shortening across the High Atlas Mountains involved a partitioning of strain, with the greatest magnitude of shortening occurring along the margins of the High Atlas Mountains.

title: Superposed folding resulting from inversion of a synrift accommodation zone, Atlas Mountains, Morocco
abstract: Copyright 2004, American Association of Petroleum Geologists. See also: http://atlas.geo.cornell.edu/morocco/publications/beauchamp2004.htmThe conspicuous offset of the northern margin of the High Atlas Mountains is composed of several large superposed folds, one of which is known as the Ait Attab Syncline. The original northeast-trending syncline (F1) was folded by a second set of fold axes (F2) that trend to the northwest. The superposed folding was generated by one phase of compression, with thrusting of synrift rocks northwestward over a prior accommodation zone formed during rifting. This accommodation zone is expressed in the exposure of synrift rocks, the exposure of Paleozoic strata in the footwall, and a coincident offset of topography. Inversion was accomplished by the transport of synrift strata along reactivated normal faults and newly formed thrusts. The unique pattern of refolding is believed to be characteristic of inversion.

title: An integrated geophysical investigation of recent seismicity in the Al-Hoceima region of North Morocco
abstract: Copyright 1997, SSA. See also: http://www.seismosoc.org/publications/bssa-toc.html; http://atlas.geo.cornell.edu/morocco/publications/calvert1997.htmData produced by the Moroccan national seismological network and marine seismic reflection profiles are used to investigate the most seismically active region in Morocco, located on the Mediterranean coast at the intersection of the Rif mountain belt and the submarine Alboran Ridge. This region, in the vicinity of the city of Al-Hoceima, marks an east-west transition in the marine and land deformation styles of the distributed plate boundary between Africa and Iberia, and was the site of a Mw=6.0 earthquake on May 26, 1994.

The epicenter of the Al-Hoceima earthquake is relocated onshore, refining the initial submarine location close to the Alboran Ridge. The spatial distribution of foreshocks and aftershocks shows a NE-SW trend that continues partly offshore and is subparallel to the earlier, yet still prominent, Miocene geologic structural trend. The predominantly strike-slip focal mechanism for the Al-Hoceima event is characteristic of earthquakes in the region. Marine seismic reflection profiles, that intersect the offshore region of seismicity, image active high angle faults with possible strike-slip components. The seismicity trend is not directly related to the submarine Alboran Ridge or the geomorphologically prominent Nekor fault. Deformation appears to be occurring on a number of subsidiary strike-slip faults that together compose a NE-SW zone of distributed shear.

The distributed strike-slip and documented normal faulting taking place in the eastern Rif mountains, although characteristic of the Rif region, are in contrast to the thrusting style of deformation that occurs farther to the east in the Algerian Tell Atlas. This may be related to the reported lateral variations and evolution of the convergent plate boundary in these regions during the Neogene and Quaternary times.

title: Geodynamic evolution of the lithosphere and upper mantle beneath the Alboran region of the western Mediterranean: Constraints from travel time tomography
abstract: An edited version of this paper was published by the American Geophysical Union. Copyright 2000, AGU. See also: http://www.agu.org/pubs/crossref/2000/2000JB900024.shtml; http://atlas.geo.cornell.edu/morocco/publications/calvert2000.htmA number of different geodynamic models have been proposed to explain the extension that occurred during the Miocene in the Alboran Sea region of the western Mediterranean despite the continued convergence and shortening of northern Africa and southern Iberia. In an effort to provide additional geophysical constraints on these models, we performed a local, regional, and teleseismic tomographic travel time inversion for the lithospheric and upper mantle velocity structure and earthquake locations beneath the Alboran region in an area of 800 x 800 km^2. We picked P and S arrival times from digital and analog seismograms recorded by 96 seismic stations in Morocco and Spain between 1989 and 1996 and combined them with arrivals carefully selected from local and global catalogs (1964-1998) to generate a starting data set containing over 100,000 arrival times. Our results indicate that a N-S line of intermediate depth earthquakes extending from crustal depths significantly inland from the southern Iberian coat to depths of over 100 km beneath the center of the Alboran Sea coincided with a W to E transition from high to low velocities imaged in the uppermost mantle. A high-velocity body, striking approximately NE-SW, is imaged to dip southeastwards from lithospheric depths beneath the low-velocity region to depths of ~350 km. Between 350 and 500 km the imaged velocity anomalies become more diffuse. However, pronounced high-velocity anomalies are again imaged at 600 km near an isolated cluster of deep earthquakes. In addition to standard tomographic methods of error assessment, the effects of systematic and random errors were assessed using block shifting and bootstrap resampling techniques, respectively. We

interpret the upper mantle high-velocity anomalies as regions of colder mantle that originate from lithospheric depths. These observations, when combined with results from other studies, suggest that delamination of a continental lithosphere played an important role in the Neogene and Quaternary evolution of the region.

title: Propagation of regional seismic phases (Lg and Sn) and Pn velocity structure along the Africa-Iberia plate boundary zone
abstract: An edited version of this paper was published by Blackwell Publishing. Copyright 2000, Blackwell Publishing. See also: http://www.blackwell-synergy.com/doi/abs/10.1046/j.1365-246x.2000.00160.x; http://atlas.geo.cornell.edu/morocco/publications/calvert2000GJI.htmWe used over 1000 regional waveforms recorded by 60 seismic stations located in northwest Africa and Iberia to map the efficiency of L g and Sn wave propagation beneath the Gulf of Cadiz, Alboran Sea and bounding Betic, Rif and Atlas mountain belts. Crustal attenuation is inferred from the tomographic inversion of L g/Pg amplitude ratios. Upper mantle attenuation is inferred from maps of Sn propagation efficiency derived by inversion of well-defined qualitative efficiency assignments based on waveform characteristics. Regions of L g attenuation correlate well with areas of thinned continental or oceanic crust, significant sedimentary basins, and lateral crustal variations. Comparison of the Sn efficiency results with velocities obtained from an anisotropic Pn traveltime inversion shows a fairly good correlation between regions of poor Sn efficiency and low Pn velocity. A low Pn velocity (7.6?7.8 km s-1) and significant Sn attenuation in the uppermost mantle is imaged beneath the Betics in southern Spain, in sharp contrast to the relatively normal Pn velocity (8.0?8.1 km s-1) and efficient Sn imaged beneath the Alboran Sea. Slow Pn velocity anomalies are also imaged beneath the Rif and Middle Atlas in Morocco. We do not identify any conclusive evidence of lithospheric-scale upper mantle attenuation beneath the Rif, although the crust in the Gibraltar region appears highly attenuating, making observations at stations in this region ambiguous. Paths crossing the Gulf of Cadiz, eastern Atlantic and the Moroccan and Iberian mesetas show very efficient Sn propagation and are imaged with high Pn velocities (8.1?8.2 km s-1). The spatial distribution of attenuation and velocity anomalies lead us to conclude that some recovery of the mantle lid beneath the Alboran Sea must have occurred since the early Miocene episode of extension and volcanism. We interpret the low velocity and attenuating regions beneath the Betics and possibly the Rif as indicating the presence of partial melt in the uppermost mantle which may be underlain by faster less attenuating mantle. In the light of observations from other geophysical and geological studies, the presence of melt at the base of the Betic crust may be an indication that delamination of continental lithosphere has played a role in the Neogene evolution of the Alboran Sea region.

title: Active tectonics of the western Mediterranean: Geodetic evidence for roll back of a delaminated subcontinental lithospheric slab beneath the Rif Mountains, Morocco
abstract: Copyright 2006, Geological Society of America. See also: http://www.geosociety.org; http://atlas.geo.cornell.edu/morocco/publications/fadil2006.htmSurface deformation in Morocco derived from five years of GPS survey observations of a 22-station network, four continuously recording GPS stations, and four IGS stations in Iberia indicate roughly southward motion (~3 mm/yr) of the Rif Mountains, Morocco relative to

stable Africa. Motion of the Rif is approximately normal to the direction of Africa-Eurasia relative motion, which is predominantly strike slip, and results in shortening of the Rif and subsequent crustal extension of the adjacent Alboran Sea region. The sense, and the N-S asymmetry of the observed deformation (i.e., no evidence for north-directed shortening in the Betic Mountains north of the Alboran Sea) cannot be easily explained in terms of crustal plate interactions suggesting that dynamic processes below the crust are driving the recent geologic evolution of the western Mediterranean. The model that best fits the observations involves delamination and southward roll back of the African lithospheric mantle under the Alboran and Rif domains.

title: Crustal shortening and vertical strain partitioning in the Middle Atlas Mountains of Morocco
abstract: Copyright 1998, American Geophysical Union. See also: http://www.agu.org/pubs/crossref/1998/98TC01439.shtml; http://atlas.geo.cornell.edu/morocco/publications/gomez1998.htmThe NE-SW trending Middle Atlas Mountains of Morocco are obliquely oriented within the late Cenozoic regional stress field, resulting in deformation that is partitioned into strike-slip faulting and thrust-related folding. In the central Middle Atlas, thrusting is confined to a 20 km wide fold belt between two relatively rigid crustal blocks that are obliquely converging. We suggest that in addition to strain partitioning observed in plan view, a partitioning of deformation between the upper and lower crust may be necessary to reconcile estimated crustal thickening and horizontal shortening within the fold belt. Cross-section balancing based on field observations demonstrates a relatively modest amount of Cenozoic horizontal shortening (~ 4.7 km) normal to the fold belt producing 800 m of structural relief. Yet, the geophysical data suggest this contraction has not produced a significant crustal root beneath the fold belt; that is, the belt does not appear to be isostatically compensated. Assuming all horizontal shortening was accommodated by crustal thickening beneath the fold belt implies much greater thickening than is suggested by constraints on the preshortened crustal thickness. It thus appears that thickening does not accommodate all of the contraction. We suggest one possible solution: The upper crust shortens by thickening (faulting and folding), whereas the lower crust deforms laterally.

See also: http://www.geolsoc.org.uk/template.cfm?name=journals_jgs_home_page; http://atlas.geo.cornell.edu/morocco/publications/gomez1996.htmGeological field observations are integrated with digital topography, LANDSAT imagery, and earthquake focal mechanisms to investigate the Middle and Late Quaternary tectonism in the intracontinental Middle Atlas mountain belt in northern Morocco. The NE-SW-trending Middle Atlas Mountains, approximately 80 km in width and about 200 km long, are part of the Atlas system of northwestern Africa and represent an inverted rift that developed into an intracratonic mountain system in the foreland of the Alpine collisional zone. The Middle Atlas is composed of two provinces, the Folded and Tabular Middle Atlas, representing the palaeo-rift and a flank of the palaeo-rift, respectively. Evidence

for Late Quaternary tectonism is provided by the analysis of stream morphology in addition to geological relations. Kinematic analysis of fault-slip data and earthquake focal mechanisms demonstrate the coexistence of both extensional and compressional deformation in different areas of the Middle Atlas with a common sinistral component of slip along NE-SW-striking fault zones. Compressional features dominate the Folded Middle Atlas, whereas extension predominates in the Tabular Middle Atlas. Extension is also manifested by widespread Middle to Late Quaternary alkali volcanism. The observed kinematic variations appear to correlate with the Mesozoic palaeogeography; one possible model may involve tectonic escape. This suggests that differences in the structures inherited from the Mesozoic and Palaeozoic may influence the responses of the different regions to the Cenozoic Alpine collision between Europe and northwest Africa.

title: Structure and evolution of the Neogene Guercif Basin at the junction of the Middle Atlas Mountains and the Rif thrust belt
abstract: Copyright 2000, AAPG. See also: http://www.aapg.org/bulletin/index.cfm; http://atlas.geo.cornell.edu/morocco/publications/gomez2000AAPG.htmThe Guercif basin of northern Morocco occupies a 50 x 60 km area where the transpressional Middle Atlas mountains terminate and abut the Rif thrust belt. Analysis of over 800 km of 2-D (two-dimensional) seismic reflection profiles and eight exploratory wells, in combination with existing geological data, suggests a late Miocene episode of extension (4%, or 1.7 km, maximum) and a subsequent episode of contraction since the end of the Miocene. Most of the late Miocene deposition was concentrated in a narrow graben (herein referred to as the Guercif graben), which contrasts with the wider physiographic expression of the basin today. Geohistory analysis indicates that tectonic subsidence persisted until the Messinian, and sediment loading continued to drive subsidence even after extension stopped. Timing constraints demonstrate the contemporaneity of the Guercif graben and west-southwest-vergent thrust tectonics of the Rif thrust belt. Similar timing and proximity with the Rif, as well as the graben geometry, suggest that extension in the Guercif basin, in addition to other smaller extensional basins in the northern Middle Atlas region adjacent to the Rif, may represent the distal effects of a broad lateral shear zone bounding the thrust belt.
The Neogene Guercif basin is superimposed on the Mesozoic Middle Atlas rift, which experienced basin inversion during the Cenozoic, and seismic reflection interpretations in the southern Guercif basin depict old Mesozoic rift faults reactivated as reverse faults. Unconformities illustrate that the uplift of the Middle Atlas appears to be primarily a late Cenozoic phenomenon. The Guercif basin offers a special opportunity for petroleum exploration within an aborted rift basin such as the Middle Atlas. Mesozoic source rocks in the Middle Atlas may have been sufficiently buried beneath Neogene basin sediments to reach maturity, and the late Cenozoic timing of contraction can produce suitable structural traps.

title: Role of the Atlas Mountains (northwest Africa) within the African-Eurasian plate boundary zone
abstract: This paper was published in Geology by the Geological Society of America (GSA), and GSA retains the copyright. Geological Society of America, P.O. Box 9140, Boulder, CO 80301-9140 See also: http://www.geosociety.org; http://atlas.geo.cornell.edu/morocco/publications/gomez2000Geology.htmThe magnitudes and timing of deformation in the intracontinental Atlas Mountains of northern Africa suggest that the Atlas Mountains have been an integral part of the African-Eurasian plate-boundary zone in the western

Mediterranean during the Cenozoic. Shortening of the Moroccan Atlas has accommodated 17%?45% of the total African-Eurasian plate convergence since the early Miocene, whereas the majority of the plate convergence is accommodated in the Rif-Betic-Alboran region. Although the latter underwent other geodynamic processes, as demonstrated by extension of the Alboran Sea contemporaneous with plate convergence, shortening directions in the Atlas are generally consistent with ongoing plate convergence and show no influence of these additional processes. In the framework of plate tectonics, the western Mediterranean region, including the Atlas system, should be regarded as a diffuse plate boundary in which the Atlas Mountains comprise narrow deformable zones bounding larger, relatively rigid crustal blocks. The deformable zones reflect the influence of crustal structures inherited from a major early Mesozoic episode of intracontinental rifting in the Atlas.

title: Lithospheric seismic velocity discontinuities beneath the Arabian Shield
abstract: An edited version of this paper was published by the American Geophysical Union (AGU). Copyright 1998, AGU. See also: http://www.agu.org/pubs/crossref/1998/98GL02214.shtml; http://atlas.geo.cornell.edu/SaudiArabia/publications/Sandvol1998.htmWe determined crustal and lithospheric mantle velocity structure beneath the Arabian Shield through the modeling of receiver function stacks obtained from teleseismic P waves recorded by the 9 station temporary broadband array in western Saudi Arabia. The receiver function deconvolution technique was used to isolate the receiver-side PS mode conversions. A grid search method, which should yield an unbiased global minimum, was used to solve for a shear wave velocity model that is optimal and has the minimum number of layers needed to fit the receiver function waveform. Results from this analysis show that the crustal thickness in the shield area varies from 35 to 40 km in the west, adjacent to the Red Sea, to 45 km in central Arabia. Stability tests of each solution indicate that the models are relatively well constrained. We have also observed evidence for a large positive velocity contrast at sub-Moho depths at four stations at depths of 80 to 100 km. This discontinuity may represent a change in rheology in the lower part of the lithosphere or remnant structure from the formation of the Arabian Shield.

title: Regional discrimination of chemical explosions and earthquakes: A case study in Morocco
abstract: Copyright 1997, Seismological Society of America. See also: http://www.seismosoc.org/publications/bssa-toc.html; http://atlas.geo.cornell.edu/morocco/publications/plafcan1997.htmTo examine the limitations in the techniques for discriminating between chemical explosions and earthquakes at local and regional distances, we have applied several standard heuristics to seismic events in northwest Morocco where little a priori information was available. Although the eight Oud Zem phosphate mine explosions have similar geographic locations, total charge size, and presumably ripple-fired mechanisms, the seismic recordings are characterized by a surprising amount of diversity. Time and path independent modulations, due to the periodic source mechanism of the ripple-fired explosions, rarely unequivocally distinguish the explosions from the earthquakes. Our findings imply that more often than the current literature suggests, source inconsistencies such as differing blasting arrangements have a role in the failure of common discriminants. Furthermore, crustal seismic velocity and the attenuation structure seemed to shape the seismic signals more than the nature of the source mechanism, although site effects could not be ruled out. The 10- to 15-Hz Pg/Sg ratio test proved to be the most precise and accurate discriminant. Popular intraphase spectral and cross-spectral ratios performed considerably worse. Finally, we argue that a regional case-based approach requires extensive

regional information to meet the demanding verification goals of the Comprehensive Test Ban Treaty.

title: Tug Hill Tomorrow Land Trust Strategic Land Conservation Plan
abstract: Over the Fall semester of 2006, 13 graduate students undertook the task of creating a Strategic Conservation Plan for Tug Hill Tomorrow Land Trust (THTLT), based in Watertown, NY. The plan features a series of natural resource inventories as well as a scenic viewshed analysis of the 1.3 million acre Tug Hill plateau. Regional land use history and demographic trends are explored. Using the resource inventories a vision conservation infrastructure was created for featuring recreational corridors, river corridors and wildlife areas. To help land trust decision makers in selecting solid conservation projects, a GIS suitability model was created based the land trust's own land protection criteria. Focus areas or high priority areas for pro-active conservation were outlined and tested using the suitability model. Finally, the Cornell team identified several tools for implementation based on the condition of four separate regions of Tug Hill.Department of City and Regional Planning at Cornell, Tug Hill Tomorrow Land Trust, Land Trust Alliance, New York State Conservation Partnership, Grant Program and the Snow Foundation.

title: Sn to Sg conversion and focusing along the Atlantic margin, Morocco: Implications for earthquake hazard evaluation
abstract: Copyright 1993, American Geophysical Union. See also: http://www.agu.org/journals/gl/; http://atlas.geo.cornell.edu/morocco/publications/seber1993.htmDigital data from a telemetered, short-period seismic network in Morocco provide a new perspective for understanding the cause of severe shaking and macroseismic reports in Morocco produced by large, offshore earthquakes located along the Azores-Gibralter seismic zone. Even though the earthquake epicenters are 500-1000 km away from the Moroccan coast, historical records show that such events are capable of producing considerable damage in inland areas. We analyze 15 earthquakes that occurred in this region. The records show multiple S phases with varying frequencies and amplitudes. The S phase with the largest amplitude, usually misinterpreted as Sn, has a phase velocity of 4.2-4.4 km/s. We show that these S arrivals can best be explained as Sn to Sg converted phases. Calculated locations of the conversion points for these phases exhibit two distinct zones almost parallel to the Atlantic coastline: one is located along the passive continental margin and the other is located about 100 km inland from the coastline. We interpret these two zones to be regions where a sudden change in crustal thickness occurs. Such zones act to focus and magnify the amplitudes of seismic phases. This interpretation explains the unusually strong felt reports within Morocco from such distant offshore events, and it has a significant effect on earthquake hazard evaluation and mitigation studies.

title: Geophysical evidence for lithospheric delamination beneath the Alboran Sea and Rif-Betic

mountains
abstract: This paper was published in Nature by the Nature Publishing Group (NPG), and NPG retains the copyright. See also: http://www.nature.com/nature/journal/v379/n6568/abs/379785a0.html; http://atlas.geo.cornell.edu/morocco/publications/seber1996Nature.htmGeophysical evidence is presented for an episode of active delamination of a piece of continental lithosphere. Observations of earthquake hypocentre locations, seismic wave velocities and attenuation, Bouguer gravity, seismic reflection, and drill hole data are combined with surface geology to infer the presence of a high-velocity, seismically active, rigid body in the upper mantle beneath the Alboran Sea and surrounding Betic and Rif mountain belts of the western Mediterranean region. This upper-mantle body, inferred to be the delaminating continental lithosphere, is overlain by a low-velocity, aseismic and strongly attenuating uppermost mantle, inferred to be the asthenospheric material replacing the delaminating lithosphere.

title: Southern Madison Heritage Trust Strategic Land Protection Plan
abstract: Over the Fall semester of 2005, 12 graduate students undertook the task of creating a Strategic Land Protection Plan for the Southern Madison Heritage Trust (SMHT), a land trust based in Hamilton, NY. The Strategic Land Protection Plan is a bold vision. The plan is based on demographic research and inventories of both natural and scenic resources. Using these inventories, suitability models in GIS were created to display various land protection scenarios. Taking advantage of the New York State Canal Corporation’s proposal for an Empire State Greenway building on the historic Erie Canal network, the students crafted a proposed greenway for recreational uses, natural resource functions and growth management. As the Chenango Canal is an integral part of the proposed greenway, the long term protection of this corridor is major concern for SMHT. Within the proposed greenway, the students modeled a greenbelt surrounding the four major municipalities that is designed to allow growth while protecting the gateways to the villages, surrounding farmland and biodiversity of the region. The conservation of the proposed 16,000 acre greenbelt can be achieved through the use of regulatory tools, transfer of lands from key partners to SMHT, improved land management by private landowners as well as the exercise of real estate tools used by SMHT such as securing easements through outright purchase or donation from willing landowners.Department of City and Regional Planning at Cornell University, Southern Madison Heritage Trust

title: Dynamic Optimization Model for a Lignocellulosic Biorefinery Supply Chain
abstract: Lignocellulosic biorefining system studies have not adequately addressed the integrated nature of the supply chain from feedstock source (farms) to product demand points. The literature typically focuses on systems of single processing facilities with a tendency to study the agricultural side of the supply chain and dismiss the product distribution considerations, such as proximity to demand centers, other processing facilities, or the nature of product market demand.
This study offers a more holistic approach by modeling the supply chain from multiple agricultural production sources (farms) to multiple biorefineries, as well as the product distribution to multiple demand locations. The objectives are to establish a dynamic modeling framework for a biorefinery supply chain and to illustrate the use of that framework. The model is designed with the following considerations in mind. 1) Which feedstocks should be purchased? 2) When and from where should they be purchased? 3) Where, how much, and how long should feedstocks be stored? 4) Where, when, how many, and how large should the biorefineries be built? 5) How much and when should the products be produced? 6) How much and where should the products be distributed? 7) How should processing capacity expand over time?
The modeling methodology employs a dynamic mathematical program. The supply chain is defined by a system of constraint expressions and optimized by maximizing total system profit. The profit function is defined to include product revenue and system costs, such as feedstock costs, transportation costs, and operating costs. The factors influencing the parameterization of the model are discussed and example parameter values are given. The model is validated and executed to obtain an example solution. The results are presented and discussed to illustrate how the modeling framework can be used to help support biorefinery system planning decisions.
This original contribution shows that biorefinery supply chains modeled to incorporate the interactions between multiple farms, biorefineries, and demand locations can provide insights that would not be possible with single system studies or ?supply side only? models. It is shown that mathematical programming offers useful tools for biorefinery supply chain studies. Topics for further research are discussed.

title: The role of culture in the process of coping with stress.
abstract: This study explored coping as a cultural adaptation by studying the role of ethnicity and acculturation stage in shaping coping strategies. One hundred and twenty eight Asians and 155 participants of European descent filled out a survey measuring their length of US residence, coping strategies and psychological distress. Findings revealed that ethnicity interacted with stages of acculturation in influencing coping choice. However, this process worked differently for different coping categories. As acculturation increases, Asians and Europeans became more similar in their use of personal coping resources through problem solving and cognitive restructuring. However, their utilization of social resources such as support seeking became more distinct. This can be attributed to differences in acculturation success and distress associated with social relatedness. Thus, culture serves as both a person variable and a contextual variable in influencing coping choice.College grant of Human Ecology at Cornell University

title: New Approaches For Identifying Critical Integrin-Mediated Signaling Events In Directed Cell Migration
abstract: Dynamic regulation of cell adhesion on extracellular matrix (ECM) proteins plays vital roles in the establishment and maintenance of tissue structure. More specifically, the spatial coordination of cell-ECM adhesion foci, or focal contacts, influences direction-sensing in motile cells for a wide range of biological processes in metazoan life. Currently available evidence suggests that positive feedback loops between a few canonical signaling pathways focuses rapid turnover of focal contacts at the leading edge, where broad protrusions guide cells in one direction or another. For instance, Rho GTPases regulate the localization of specific actin cytoskeletal rearrangements, phosphatidylinositol 3-kinase (PI3K) -generated second messengers facilitate polarization of related signaling molecules, and focal adhesion kinase (FAK) may potentially act as a mediator of these distinct signaling pathways. This dissertation aims to elucidate mechanisms that coordinate these signaling pathways, with acknowledgement of the limitations of current methods in studying cell migration (Chapter 1).
To address questions relating to the role of certain signaling molecules in the maintenance of direction in migration, novel methods for depositing gradients of ECM molecules have been established, including one novel technique incorporating microfluidics, which is amenable to live cell tracking via standard microscopy (Chapter 2). This microfluidic device enables the relative impact of the overexpression of various key proteins to be examined. The subsequent study suggests the role of FAK in facilitating maintained directional migration, also described as persistent migration (Chapter 3). These results suggest that FAK is a critical facilitator of direction-sensing and spatial regulation of focal contacts.

title: Organic Chemicals in Sewage Sludges
abstract: Sewage sludges are residues resulting from the treatment of wastewater released from various sources including homes, industries, medical facilities, street runoff and businesses. Sewage sludges contain nutrients and organic matter that can provide soil benefits and are widely used as soil amendments. They also, however, contain contaminants including metals, pathogens, and organic pollutants. Although current regulations require pathogen reduction and periodic monitoring for some metals prior to land application, there is no requirement to test sewage sludges for the presence of organic chemicals in the U. S. To help fill the gaps in knowledge regarding the presence and concentration of organic chemicals in sewage sludges, the peer-reviewed literature and official governmental reports were examined. Data were found for 516 organic compounds which were grouped into 15 classes. Concentrations were compared to EPA risk-based soil screening limits (SSLs) where available. For 6 of the 15 classes of chemicals identified, there were no SSLs. For the 79 reported chemicals which had SSLs, the maximum reported concentration of 86% exceeded at least one SSL. Eighty-three percent of the 516 chemicals were not on the EPA established list of priority pollutants and 80% were not on the EPA's list of target compounds. Thus analyses targeting these lists will detect only a small fraction of the organic chemicals in sludges. Analysis of the reported data shows that more data has been collected for certain chemical classes such as pesticides, PAHs and PCBs than for others that may pose

greater risk such as nitrosamines. The concentration in soil resulting from land application of sludge will be a function of initial concentration in the sludge and soil, the rate of application, management practices and losses. Even for chemicals that degrade readily, if present in high concentrations and applied repeatedly, the soil concentrations may be significantly elevated. The results of this work reinforce the need for a survey of organic chemical contaminants in sewage sludges and for further assessment of the risks they pose.

title: Constructing Order amid Violence: Comparative Military Interventions in the Era of Peacekeeping and Counter-Terrorism
abstract: This study is motivated by two questions: To what extent are countries engaged in military interventions willing to use force to promote democracy? And what are the likely consequences of such actions? Interveners face a dilemma in seeking to impose democracy through military interventions: They can either accommodate armed factions in the target state by bringing them into a powersharing government with little democratic accountability, or they can seek to impose higher-order democracy at the risk of violent confrontation. The course of action chosen depends on the interveners' regime types, strategic cultures, and resource constraints. Coalitions dominated by committed democracies with militarized strategic cultures have proven vastly more successful in promoting democratic change through interventions than coalitions dominated by less militarized, less committed, or less democratic states. They do so, however, at the risk of provoking international crises and unsustainable escalations of violence. These claims are investigated through both a medium-N, fuzzy-set analysis of all military interventions in the post-Cold War era and a series of controlled, focused comparisons between the policies of the United States, Germany, and Russia in interventions in the Balkans and Central Asia. This study has implications for both theory and policy. It advances the argument that both rationalist and constructivist theories of international relations, taken separately, fail to predict either state behavior or the outcomes of states' policy choices; rather, only by integrating these perspectives can we understand patterns of military interventions. These patterns reveal that policy-makers must commit to one of three basic models of intervention; pursuing the goals of one while providing the means appropriate to another typically yields disastrous outcomes.

title: Three-dimensional upper mantle structure beneath the intraplate Atlas and interplate Rif mountains of Morocco
abstract: Copyright 1996, American Geophysical Union. See also: http://www.agu.org/pubs/crossref/1996/95JB03112.shtml; http://atlas.geo.cornell.edu/morocco/publications/seber1996JGR.htmWe integrate observations based on teleseismic P wave travel times and available geologic data to infer that the lithosphere beneath the intraplate Atlas mountains is thin and/or it is characterized by lower P wave velocities,

while beneath the interplate Rif mountains and the adjacent Alboran Sea a previously thickened lithosphere has been delaminated into the upper mantle. Using surface geology and geochronology data, previous studies have proposed that lithospheric delamination took place in this region. In thsi study we show through analysis of teleseismic P wave residuals the existence of a high velocity (>3%) upper mantle body, which is interpreted to be the delaminated, rigid lithosphere. This high-velocity layer is overlain by a very low velocity uppermost mantle material replacing the delaminated lithosphere. Teleseismic P waves recorded by a recently installed digital seismic network and an older analog network in Morocco provide the residuals database. A total of 734 P wave residuals from 92 selected teleseismic earthquakes are used to document the spacial pattern of upper mantle velocity structure beneath northern Morocco and the Alboran Sea. Subsequent use of these residuals in a tomographic inversion scheme produced a three-dimensional velocity image of the upper mantle. We infer from the P residuals that strong upper mantle velocity anomalies exist beneath both the Rif and Atlas regions. The Rif stations show negative residuals (- 1-1.5s) for ray paths from the east and northeast and show positive residuals (~ 1-1.5s) for raypaths from the northwest and southwest. Tomographic results indicate the existence of a high-velocity body (~ 3% higher velocities) in the upper mantle beneath the eastern Rif and Alboran Sea, extending approximately from subcrustal depths down to a depth of at least 350 km. In the western Rif, however, 1-2% lower velocity material is imaged in the upper mantle. The residuals of the Atlas stations also show azimuthal variations. In general, most of the P waves that travel beneath the High and Middle Atlas have about 0.5-1.0s delays. In contrast, the rays that travel beneath the northwestern margin of the Atlas mountains and the adjacent Moroccan Meseta area show negative residuals (~1s), suggesting that higher velocity material exists beneath the platform area adjacent to the Atlas mountains. Tomographic results indicate that beneath most of the Atlas system the uppermost mantle has about 1% lower velocities. Beneath the Alboran Sea region, however, reported low uppermost mantle Pn velocities contrast strongly with higher velocity upper mantle velocities obtained by our analysis. Low-velocity uppermost mantle beneath the Alboran Sea underlain by a high-velocity upper mantle material is used to support earlier interpretations of lithospheric delamination beneath the Rif and Alboran Sea Regions. The enigmatic occurrence of subcrustal earthquakes in these regions is also consistent with this active delamination mechanism.

title: Land Application of Sewage Sludges: An Appraisal of the US Regulations
abstract: This paper was published in the peer reviewed INT. J. OF ENVIRONMENT AND POLLUTION, 1999, Vol. 11 No. 1 pp 1-36. The journal is available in both hard copy and on-line PDF format. For more information and sample copy of IJEP, visit their web site at http://www.inderscience.com/.Current US federal regulations governing the land application of sewage sludges do not appear adequately protective of human health, agricultural productivity or ecological health. US standards are far less protective than those of many European countries and Canadian provinces. This is due to both policy choices such as a ''do no harm'' philosophy applied in some northern European countries and also to many gaps and non-conservative assumptions in the risk assessment performed by US Environmental Protection Agency. The potential for widespread use of sludges on agricultural and residential land, the persistence of many of the pollutants, which may remain in soils for a very long time, and the difficulty of remediation support a cautious approach. Soil, water and crop characteristics in New York State and other areas of the northeastern US raise particular concerns. The authors do not suggest a prohibition of land application but, rather, significantly more restrictive use. Limiting cumulative additions of pollutants to prevent soils from exceeding recommended maximum contaminant levels can be achieved by application of clean sludges or by application of lesser amounts of less high quality sludges. Further investigation is needed to assess risks to ground and surface water and to establish standards for additional contaminants.

title: Experimental Eulerian and Lagrangian investigations in simple turbulent flows
abstract: This thesis consists of three parts.

The first part consists of a study of high-Reynolds number, homogeneous, isotropic turbulence in wind tunnels which has been strained via an axi-symmetric contraction. The effect of strain on the turbulence is studied by detailed hot-wire measurements. The results are compared with Rapid Distortion Theory (RDT). The return to isotropy of the strained turbulence is studied and compared with Rotta's linear theory. The effect of strain on intermittancy as well as the structure of turbulence is also studied.

In the second part the experimental measurements of inertial particle Lagrangian accelerations are described. These are the first measurements of inertial particle accelerations in a well documented high-Reynolds number wind-tunnel flow. Using a high-speed camera which moves with the mean speed of the flow, inertial particle trajectories are obtained. The trajectories are analyzed to obtain the particle accelerations. The acceleration probability distribution functions (PDFs) are compared with those of recent computer simulations.

The last part consists of an analysis of inertial particle motion in turbulent flows. A new model called the Vortex model is proposed and used to study the inertial particles in turbulent-like flows. Using this model, several mechanisms through which attenuation of inertial particle accelerations may occur in real turbulent flows are studied. We also compare the results of the Vortex model with those of the DNS simulations of Bec et al. [\textit{J. Fluid Mech} \textbf{550} (2006)]. The range of applicability and shortcomings of stochastic acceleration models for inertial particle modeling are also discussed.

The results of this work have a wide range of applicability. The complex spectral dynamics associated with relatively simple straining flow and subsequent relaxation which is found in many engineering and natural flows is explored in detail. These results can be used to build better models for strained flows. Inertial particle accelerations are suspected to play major roles in determining rain drop formations, particle agglomeration in industrial flows, pollutant transport and other related phenomena. The modeling and experimental results will aid in developing more accurate models of inertial particle dynamics.

title: Simulating the Impacts of Agroterrorism on U.S. Financial Markets and Regional Economic Performance
abstract: The threat of terrorism against the United States has been a primary concern of public policy makers, particularly after the attacks of September 11, 2001. Economic theory and statistical analysis provide valuable insights into the challenge of estimating the regional and national economic impacts of future attacks. Terrorist events represent exogenous shocks on the economy which can cause significant emotional and psychological damage. The initial chapters describe a simulation model that captures the impacts of agricultural terrorism (agroterrorism) on the economic performance of various sectors within a regional economy, while the final chapters examine the impacts of agroterrorism on U.S. financial markets.

I begin the analysis by examining the probable direct and indirect economic impacts of bioterrorism originating in St. Lawrence County, New York. The specific biological weapon examined is a foot-and-mouth disease (FMD) attack that disrupts the local agricultural food supply. A county-level simulation is valuable because it focuses on the immediate impact of FMD, providing useful estimates of the short-to-medium term impacts. The regional model contains in depth analysis of the livestock industry with specific links to

regional tourism, and the results section includes impact estimates using a Social Accounting Matrix (SAM) framework.

St. Lawrence County serves as an interesting case study to explore supply-chain linkages, since the region depends heavily on its livestock and tourism industries which would suffer following an FMD attack. I perform simulations assuming that the attack has no direct impact on dairy farm products, before relaxing this assumption to account for economic impacts associated with parallel shocks to the livestock and dairy industries. The methodology focuses on estimating the economic implications of production and trade disruptions in the international market. The costs of agroterrorism are estimated in terms of disruptions to regional output, employment, and value added for key sectors within the economy. I provide impact assessments for livestock, tourism, dairy, and all sectors within the region.

The direct costs of the attack within the region would reflect the initial output reductions, and the indirect costs would reflect changes in inter-industry transactions as supplying industries react to falling demand from the directly affected industries. Indirect effects significantly increase the magnitude of losses suffered by the economy as the damage flows beyond the industries directly impacted. These indirect effects would include losses suffered by related industries, such as firms engaged in food supply, transportation, distribution, and retail. The firm-level impacts are outside the scope of this research project.

The latter chapters explore the broader impacts on financial asset classes in equities, fixed income, and foreign exchange to produce real GDP growth rate forecasts using the Global Insight macroeconomic model of the U.S. economy. By linking to the macro model following the regional analysis, we can examine the economy-wide repercussions of a terrorist attack on U.S. agriculture. I will show that a state of financial uncertainty brought forth by terrorism can decrease consumer confidence, increase interest rates, increase credit spreads, dampen the stock market, and impact the value of the U.S. dollar relative to the currencies of trading partners.

I will demonstrate that extreme terrorist events tend to disrupt the normal relationships among financial asset classes. The results section for the macro impact model includes real GDP growth rate forecasts and projected real output losses. For both the regional and national models I draw on the literature to examine the attack under various assumptions regarding the severity of output reductions. I conclude with policy recommendations based on my findings, as well as directions for future research.

title: Reasoning about Authorization Policies
abstract: An authorization policy states the conditions under which an action is permitted or forbidden. In this dissertation, we use formal methods to ensure that policies written in certain languages are unambiguous and to provide provably correct algorithms for reasoning about policies. For example, we describe how questions about entailment, such as ``may Alice edit the database?'', can be answered efficiently.

We begin by showing that a fragment of first-order logic can be used to represent and reason about policies. Because we use first-order logic, policies have a clear syntax and semantics. We show that further restricting the fragment results in a language that is still quite expressive yet is also tractable. More precisely, questions about entailment can be answered in time that is a low-order polynomial (indeed, almost linear in some cases), as can questions about the consistency of policy sets.

In addition to developing our own language, we have examined two policy languages, XrML and ODRL. We focused on these languages because, when we began our work, they seemed to have the strongest support from industry. We found that the specifications for both languages have significant problems, which is not surprising since neither includes formal semantics. We discussed the problems that we found with the language developers and then proposed formal semantics for each language. We present our semantics here.

In addition, we consider the complexity of determining if a permission is implied by a set of statements in each language. We prove that the general problem for XrML is undecidable and the general problem for ODRL is decidable and NP-hard. Finally, we define fragments of both languages that are fairly expressive and for which the problem is polynomial-time computable.

title: The 1759 earthquake in the Bekaa valley: Implications for earthquake hazard assessment in the eastern Mediterranean region
abstract: Copyright 1989, American Geophysical Union. See also: http://atlas.geo.cornell.edu/deadsea/publications/Ambraseys1989_JGR.htmAnalysis of macroseismic data based on primary sources for large, though infrequent, historical earthquakes (Ms > 6.5) that occurred along an approximately 350-km-long segment of the northern part of the Dead Sea fault system primarily in Lebanon and Syria for the period 1100-1988 reveals the following: (1) Ten events occurred in three relatively short periods (tens of years) with repeat times of 200-350 years; (2) the events most probably broke this north segment of the Dead Sea fault system, possibly including the westernmost segment of the East Anatolian fault system near the border between Syria and Turkey; (3) the lack of such large events during the past 100 years should not be interpreted to minimize potential earthquake hazard in this region; and (4) the Ms ~ 7 plus earthquake on November 25, 1759, almost certainly produced surface faulting probably along the Yammouneh fault in the Bekaa valley and caused heavy destruction with great loss of life in numerous villages and towns, including Safad, Damascus, Beirut, and Baalbek. This main event was preceded by a Ms ~ 6 plus foreshock on October 30, 1759, in the southern part of the epicentral area of the main shock near the towns of Safad and Qunaitra, which were almost totally destroyed with considerable loss of life.

title: Structure and tectonic development of the Ghab Basin and the Dead Sea Fault System, Syria
abstract: This material has been published in The Journal of the Geological Society of London, Volume 158, the only definitive repository of the content that has been certified and accepted after peer review. Copyright and all rights therein are retained by The Geological Society of London. Copyright 2001, The Geological Society of London. See also: http://atlas.geo.cornell.edu/deadsea/publications/Brew2001_GSL.htmWe examine the structure and evolution of the Ghab basin that formed on the active, yet poorly understood, northern segment of the Dead Sea transform fault system. The basin formed in the Plio-Quaternary time at a complex step-over zone on the fault. Subsidence occurred along cross-basin and transform-parallel faults in two asymmetric depocentres. The larger depocentre in the south of the basin is asymmetric towards the east, the margin along which most active transform displacement apparently occurs. The Syrian Coastal Ranges, located directly west of the Ghab basin, are a consequence of Late Cretaceous and Cenozoic regional compression, heavily modified by the Dead Sea fault system and Ghab basin formation. We prefer a model whereby the Dead Sea fault system in northwest Syria developed in Plio-Quaternary time, consistent with previously proposed models of two-phase Dead Sea fault system movement and Red Sea spreading.

title: Late Cenozoic uplift along the northern Dead Sea transform in Lebanon and Syria
abstract: An edited version of this paper was published in Earth and Planetary Science Letters by Elsevier Science. Elsevier Science retains the copyright to this paper. Copyright 2006, Elsevier Science. See also: http:\\dx.doi.org/10.1016/j.epsl.2005.10.029; http://atlas.geo.cornell.edu/deadsea/publications/Gomez2006_EPSL.htmEvidence of long-term, late Cenozoic uplift, as well as strike-slip faulting, is revealed by topographic and geological features along the northern 500 km of the Dead Sea fault system (DSFS)- the transform boundary between the Arabian and African plates in the eastern Mediterranean region. Macro-geomorphic features are studied using a new, high-resolution (20 m pixel) digital elevation model (DEM) produced by radar interferometry (InSAR). This DEM provides a spatially continuous view of topography at an unprecedented resolution along this continental transform from 32.5 to 38 degrees N. This section of the left-lateral transform can be subdivided into a 200 km long Lebanese restraining bend (mostly in Lebanon), and the section to the north (northwest Syria). Spatial variations in Cenozoic bedrock uplift are inferred through mapping of topographic residuals from the DEM. Additionally, high altitude, low-relief surfaces are mapped and classified in the Mount Lebanon and Anti Lebanon ranges that also provide references for assessing net uplift. These results demonstrate an asymmetric distribution of post-Miocene uplift between the Mt. Lebanon and Anti Lebanon ranges. Antecedent drainages also imply that a major episode of uplift in the Palmyride fold belt postdates the uplift of the Anti Lebanon region. North of the restraining bend, the Late Miocene surface is preserved beneath spatially extensive lava flows. Hilltop remnants of this paleosurface demonstrate Pliocene-Quaternary uplift and tilting of the Syrian Coastal Range, adjacent to the DSFS north of the restraining bend. This late Cenozoic uplift is contemporaneous with strike-slip along the DSFS. Geometrical relationships between folds and strike-slip features suggest that regional strain partitioning may accommodate a convergent component of motion between the Arabian and African plates. This interpretation is consistent with regional plate tectonic models that predict 10-25 degrees of obliquity between the relative plate motion and the strike of the DSFS north of the restraining bend. We suggest that this convergent component of plate motion is responsible for uplift along and adjacent to the DSFS in the Syrian Coastal Range, as well as within the Lebanese restraining bend.

title: Holocene faulting and earthquake recurrence along the Serghaya branch of the Dead Sea fault system in Syria and Lebanon
abstract: An edited version of this paper was published in Geophysical Journal International by Blackwell Publishing. Blackwell Publishing retains the copyright. Copyright 2003, Blackwell Publishing. See also: http://www.blackwell-synergy.com/doi/abs/10.1046/j.1365-246X.2003.01933.x; http://atlas.geo.cornell.edu/deadsea/publications/Gomez2003_GJI.htmThe Serghaya fault, located approximately along the Syrian-Lebanese border, is a prominent structure within the 200 km restraining bend in the left-lateral Dead Sea fault system. This study documents palaeoseismic and geomorphic expressions of Holocene movements on the Serghaya fault based on trench excavations and radiocarbon dates. Trenches were excavated across and parallel to a 4.5 m fault scarp where Late Pleistocene sediments are faulted against Holocene alluvium and colluvium. Locally oblique slip on the Serghaya fault has produced a sequence of fault-derived colluvial wedges that distinguishes individual palaeoseismic events. In addition, the trench excavations also depict a sequence of buried and displaced channels. Our palaeoseismic study reveals evidence for five surface-rupturing events within the past ~6500 yr. The last event involved 2-2.5 m of primarily left-lateral displacement and may correspond to one of two historically documented earthquakes during the 18th century (in 1705 and 1759).

The displaced channels provide an estimated slip rate of approximately 1.4 - 0.2 mm yr-1 during the Holocene. The chronological relationships between the colluvial wedges and faulted channels demonstrate an average left-lateral displacement of about 2 m per event, suggesting that such events correspond to earthquakes of M >~ 7 with a mean return time of about 1300 yr. These results demonstrate that the Serghaya fault may present a previously overlooked earthquake hazard for populations in the vicinity of the AntiLebanon Mountains, including the cities of Damascus and Beirut. In a regional context, the inferred slip rate along the Serghaya fault accounts for about 25 per cent of the total expected motion of Arabia relative to Africa along the Dead Sea fault system. The fact that the Serghaya fault accounts for only a fraction of the expected plate motion implies that the remaining strike-slip and shortening must be accommodated by other active fault branches within the large restraining bend of the Dead Sea fault system. These results contradict suggestions that the northern Dead Sea fault system in Lebanon and Syria is presently inactive as a result of an evolving regional stress field in the eastern Mediterranean region.

title: Coseismic displacements along the Serghaya Fault: An active branch of the Dead Sea Fault System in Syria and Lebanon
abstract: This material has been published in The Journal of the Geological Society of London, Volume 158, the only definitive repository of the content that has been certified and accepted after peer review. Copyright and all rights therein are retained by The Geological Society of London. Copyright 2001, The Geological Society of London. See also: http://atlas.geo.cornell.edu/deadsea/publications/Gomez2001_JGS.htmExamination of the Serghaya fault, a branch of the Dead Sea Fault System in western Syria and eastern Lebanon, documents Late Quaternary and Recent left-lateral fault movements including the probable remnant of a historic coseismic surface rupture. Carbon-14 dating and the presence of fault-scarp free faces in soft, late Pleistocene lake deposits suggest coseismic slip during the past two or three centuries, possibly corresponding with one of the well-documented earthquakes of 1705 or 1759. With an estimated Holocene slip rate of 1-2 mm/yr, the Serghaya Fault accommodates a significant part of the active deformation along the Arabian-African plate boundary. These results suggest that multiple active fault branches are involved in the transfer of strain through the 'Lebanese' restraining bend.

title: Bouguer gravity and crustal structure of the Dead Sea transform fault and adjacent mountain belts in Lebanon
abstract: This paper was published in Geology by the Geological Society of America (GSA), and GSA retains the copyright (1993). Geological Society of America, P.O. Box 9140, Boulder, CO 80301-9140
See also: http://www.geosociety.org; http://atlas.geo.cornell.edu/deadsea/publications/Khair1993_Geology.htmThe northern extension of the Dead Sea transform fault in southern Lebanon bifurcates into several faults that cross Lebanon from south to north. The main strand, the Yammouneh fault, marks the boundary between the Levantine (eastern Mediterranean) and Arabian plates and separates the western mountain range (Mount Lebanon) from the eastern mountain range (Anti-Lebanon). Bouguer gravity contours in Lebanon approximately follow topographic contours; i.e., positive Bouguer anomalies are associated with the Mount Lebanon and Anti-Lebanon ranges. This suggests that the region is not in simple isostatic compensation.

Gravity observations based on 2.5-dimensional modeling and other available geological and geophysical information have produced the following interpretations. (1) The crust of Lebanon thins from 35 km beneath the Anti-Lebanon range, near the Syrian border, to 27 km beneath the Lebanese coast. No crustal roots exist beneath the Lebanese ranges. (2) The depth to basement is 3.5-6 km below sea level under the ranges and is 8-10 km beneath the Bekaa depression. (3) The Yammouneh fault bifurcates northward into two branches; one passes beneath the Yammouneh Lake through the eastern part of Mount Lebanon and another bisects the northern part of the Bekaa Valley (i.e., Mid-Bekaa fault). The Lebanese mountain ranges and the Bekaa depression were formed as a result of transtension and later transpression associated with the relative motion of a few crustal blocks in response to the northward movement of the Arabian plate relative to the Levantine plate.

title: Investigation of Alleged Health Incidents Associated with Land Application of Sewage Sludges
abstract: The majority of US sewage sludges are disposed by application to land for use as a soil amendment. Class B sludges, containing a complex mix of chemical and biological contaminants, comprise the majority. Residents near land application sites report illness. Symptoms of more than 328 people involved in 39 incidents in 15 states are described. Investigation and tracking of the incidents by agencies is poor. Only one of 10 EPA regions provided substantial information on the incidents in their region. Investigations, when conducted, focused on compliance with regulations. No substantial health-related investigations were conducted by federal, state or local officials. A system for tracking and investigation is needed. Analysis of the limited data suggests that surface-applied Class B sludges present the greatest risk and should be eliminated. However, even under less risky application scenarios, the potential for off-site movement of chemicals, pathogens and biological agents suggest that their use should be eliminated.

title: Evidence for 830 years of seismic quiescence from palaeoseismology, archaeoseismology, and historical seismicity along the Dead Sea fault in Syria
abstract: An edited version of this paper was published in Earth and Planetary Science Letters by Elsevier Science. Elsevier Science retains the copyright to this paper (Copyright 2003). See also: http:\\dx.doi.org\10.1016\S0012-821X(03)00144-4; http://atlas.geo.cornell.edu/deadsea/publications/Meghraoui2003_EPSL.htmThe long historical record of earthquakes, the physical effects on ancient building structures and the palaeoseismology provide a unique opportunity for an interdisciplinary tectonic analysis along a major plate boundary and a realistic evaluation of the seismic hazard assessment in the Middle East. We demonstrate with microtopographic surveys and trenching that the Dead Sea fault (DSF) offsets left-laterally by 13.690.2 m a repeatedly fractured ancient Roman aqueduct (older than AD 70 and younger than AD 30). Carbon-14 dating of faulted young alluvial deposits documents the occurrence of three large earthquakes in the past 2000 years between AD 100 and 750, between AD 700 and 1030 and between AD 990 and 1210. Our study provides the timing of late Holocene earthquakes and constrains the 6.990.1 mm/yr slip rate of the Dead Sea transform fault in northwestern Syria along the Missyaf segment. The antepenultimate and most recent faulting events may be correlated with the AD 115 and AD 1170 large earthquakes for which we estimate Mw =7.3^7.5. The 830 yr of seismic quiescence along the Missyaf fault segment implies that a large earthquake is overdue and may result in a major catastrophe to the population centres of Syria and Lebanon.

title: Remote earthquake triggering along the Dead Sea fault in Syria following the 1995 Gulf of Aqaba earthquake (Ms=7.3)
abstract: Copyright 2000, Seismological Society of America. See also: http://www.seismosoc.org/publications/srl.html;
http://atlas.geo.cornell.edu/deadsea/publications/Mohamad2000_SRL.htmOn 22 November 1995, a large (Ms=7.3) earthquake occurred in the central Gulf of Aqaba region that was felt at distances of up to 600 km. This was the largest earthquake to occur along the Dead Sea fault system (DSFS) during the 20th century. This earthquake was followed by an aftershock sequence that lasted for more than one year, with numerous shocks exceeding a magnitude of 5.0. The centroid moment tensor (CMT) location of the mainshock was 29.07?N and 34.73?E, and the hypocentral depth was about 18km.

In this study, we report a peculiar swarm of seismic activity that started within hours following the Aqaba earthquake along the DSFS about 500 km north of the mainshock location. Temporal and spacial analyses of these small to moderate-size earthquakes (M<3.7) suggest that these earthquakes were remotely triggered by the mainshock of the Aqaba earthquake.

Coseismic stress triggering of earthquakes has received considerable attention since the 1992 Landers earthquake in California (Ms=7.3) (e.g., Hill et al., 1993; King et al., 1994; JGR special issue edited by Harris, 1998). Static stress changes due to elastic loading correlate well with aftershock activity (e.g., King et al., 1994) and may be a source of triggering larger earthquakes near the original fault rupture (i.e., within one or two rupture lengths) (e.g., Harris et al., 1997). King et al. (1994) demonstrated that the sequence of moderate to large earthquakes in southern California during the ~15 years leading up to the Landers earthquake corresponds with static stress increases from each successive earthquake. A similar case has been made for the 20th century seismicity along the North Anatolian Fault system in Turkey (Stein et al., 1997).

Remote triggering was also recognized following the Landers earthquake at distances of over 1,250 km (Hill et al., 1993; Anderson et al., 1994). In such cases static stress changes appear to be negligible, but dynamic stresses still may be significant. The case we will present below shows characteristics consistent with some

predictions of dynamic “rate state” stress triggering models (Gomberg et al., 1998).

title: Law and Order in the EU: The Comparative Politics of Compliance
abstract: Why do some member states of the European Union comply with EU law more than others? The dissertation answers this question by unpacking the ?black box? of the liberal democratic state and testing three alternative hypotheses. The chief reason why some states violate law beyond the nation-state more than others is a function of the degree to which a country?s legal tradition codifies social and economic reality. As more of social and economic reality is codified into national law, the more likely a state will commit an infraction of European Union law. This argument is tested through the rigorous application of both qualitative and quantitative methods against two chief alternative explanations. Using a dataset of over 1,200 violations of the Treaty of the European Communities and its associated regulations, the statistical analysis shows that levels of codification, measured by a country?s regulatory quality, is the primary explanatory factor for both why some EU member states violate the Treaty more than others and why the ECJ is more likely to settle these legal disputes when they occur. Furthermore, even though the United Kingdom and the Federal Republic of Germany have very different legal traditions and parliamentary systems, comparing the process of compliance in each of these countries in the area of the free movement of goods shows that the degree to which basic principles of law are codified determines why they have similar proportions of infringements settled by the European Court of Justice. These findings have important implications for how we understand compliance with international law and the role domestic institutions play in the compliance process, both for the member states of the European Union and for all other states in the international system. While compliance with international law can be a normatively beneficial activity at times, it can also lead to a diminishing role for national parliaments in governing society. Most importantly, the rich diversity that democratic governance produces as it codifies social reality can be lost as international institutions homogenize national legal systems in hopes of achieving other policy goals.

title: Tomographic Pn velocity and anisotropy structure beneath the Anatolian plateau (eastern Turkey) and the surrounding regions
abstract: An edited version of this paper was published by the American Geophysical Union (AGU). Copyright 2003, AGU. See also: http://www.agu.org/pubs/crossref/2003.../2003GL017391.shtml; http://atlas.geo.cornell.edu/turkey/publications/Al-Lazki-et-al_2003.htmWe use Pn phase travel time residuals to invert for mantle lid velocity and anisotropy beneath northern Arabia eastern Anatolia continent-continent collision zone. The primary phase data were obtained from the temporary 29- station broadband PASSCAL array of the Eastern Turkey Seismic Experiment. These data were supplemented by phase data from available stations of the Turkish National Seismic Network, the Syrian National Seismic Network, the Iranian Long Period Array, and other stations around the southern Caspian Sea. In addition, we used carefully selected catalog data from the International Seismological Centre and the National Earthquake Information Center bulletins. Our results show that low (<8 km/s) to very low (<7.8 km/s) Pn velocity zones underlie the Anatolian plateau, the Caucasus, and northwestern Iran. Such low velocities are used to infer the presence of partially molten to absent mantle lid beneath these regions. In contrast, we observed a high Pn velocity zone beneath northern Arabia directly south of the Bitlis-Zagros suture indicating the presence of a stable Arabian mantle lid.

This sharp velocity contrast across the suture zone suggests that Arabia is not underthrusting beneath the Anatolian plateau and that the surface suture extends down to the uppermost mantle. Pn anisotropy orientations within a single plate (e.g. Anatolia plate) show a higher degree of lateral variation compared to Pn velocity. Areas of coherent Pn anisotropy orientations are observed to continue across major fault zones such as the EAF zone.

title: Structure and tectonic evolution of the Anatolian plateau in eastern Turkey
abstract: This paper was published by the Geological Society of America (GSA). Copyright 2006, GSA. See also: http://granite.geosociety.org/bookstore/default.asp?oID=0&catID=9&pID=SPE409; http://atlas.geo.cornell.edu/turkey/publications/Barazangi-et-al_2006.htmThe Cenozoic geology and the present lithospheric and upper mantle structure of the Anatolian plateau in eastern Turkey and nearby regions are the result of the final collision and suturing of the continental Arabian plate to the Turkish terranes (i.e., micro-continents). This process of collision and suturing was strongly influenced by three active structures in the region: the Caucasus mountains, the Aegean subduction zone, and the Dead Sea fault system. Understanding these three major tectonic elements are important for the development of a robust model for the formation of the Anatolian plateau.

We show that the Anatolian plateau lithosphere in eastern Turkey has no lithospheric mantle, i.e., the crust floats on a partially molten asthenosphere. The average thickness of the crust in the region is approximately 45 km. The uppermost mantle beneath this crustal block strongly attenuates Sn waves and has one of the lowest Pn velocities on earth (about 7.6 km/s). The Anatolian plateau, with an average of 2 km elevation is dissected by numerous active, seismogenic faults (mostly strike-slip and some thrust type). Neogene and Quaternary volcanism with varying composition is widespread and covers more than half of the region.

We argue that the northward subduction of the northern and the southern branches of the Neo-Tethyan oceanic lithosphere since the Mesozoic has resulted in the development of arc and back-arc volcanism (i.e., the Pontide and Bitlis systems) and the development of the eastern Anatolian accretionary complex that covers a large area of eastern Turkey. The northward subduction of the southern Neo-Tethys considerably thinned and weakened the overriding Eurasian plate above the descending oceanic lithosphere of the Arabian plate. The final suturing of the continental Arabian plate with the Turkish terranes in the Miocene and the continued convergence of Arabia relative to Eurasia has resulted in the shortening of the accretionary complex both in the forearc and the back-arc regions and the development of a broad zone with numerous strike-slip faults. The mobilization of the Caucasus is also partially a consequence of this convergence. The documented major episode of widespread volcanism at about 11 Ma is probably related to the breakoff of the shallowly descending oceanic segment of the Arabian lithosphere beneath eastern Turkey. The continued convergence of Arabia relative to Eurasia has resulted in the development of the North Anatolian fault (NAF) and subsequently the East Anatolian fault (EAF) in the Pliocene. At about this time, the northern segment of the Dead Sea fault (DSF) also developed in Lebanon and northwest Syria and joined the EAF to form the Anatolian - Arabian - African triple junction in the Maras region of southern Turkey. The development of these fault systems (i.e., NAF, EAF, and DSF) provided the mechanism for the tectonic escape of the Anatolian crustal block towards the Aegean arc system.

title: Sn attenuation in the Anatolian and Iranian plateau and surrounding regions
abstract: An edited version of this paper was published in Geophysical Research Letters by the American Geophysical Union (AGU). Copyright 2003, AGU. See also: http://www.agu.org/pubs/crossref/2003/2003GL018020.shtml; http://atlas.geo.cornell.edu/turkey/publications/Gok-et-al_2003.htmThe propagation characteristics of the regional Sn shear waves have been mapped to provide insight into the lithospheric structure of the Anatolian and Iranian plateau and the surrounding regions. Thousands of regional earthquakes within the distance range of 2?15 degrees were recorded by broadband and short period stations located in Turkey and nearby regions, especially new data recorded by 29 broadband stations in the Eastern Turkey Seismic Experiment network. The propagation efficiencies of Sn were determined visually using their amplitude and frequency content. Attenuation maps were then tomographically constructed using the observed propagation efficiencies. Our results confirm that Sn propagates efficiently in the uppermost mantle beneath the Mediterranean Sea, the Black Sea, and the Caspian Sea and along the Zagros fold and thrust belt. Sn is not observed in eastern Turkey, northwestern Iran, or central Anatolia. In contrast to previous available studies, this study considerably improved the mapped location of the boundaries between the zones of efficient and attenuated Sn. Our results are best explained by an absence of lithospheric mantle, or the presence of thin and hot lithospheric mantle beneath most of the Anatolian and Iranian plateau.

title: Regional wave propagation in Turkey and surrounding regions
abstract: This paper was published by the American Geophysical Union (AGU). Copyright 2000, AGU. See also: http://www.agu.org/journals/gl/gl0003/1999GL008375/pdf/1999GL008375.pdf; http://atlas.geo.cornell.edu/turkey/publications/Gok-et-al_2000.htmDigital and analog seismic waveform data collected by 34 stations in and around Turkey provided excellent ray coverage for a detailed attenuation study of regional shear waves (Sn and Lg). Over 2000 seismograms within a distance range of 15 degrees were visually inspected and the quality of Sn and Lg phases categorized into three different classes: efficient, inefficient, or not present. Our results show that Sn and Lg propagation is mostly inefficient in western Turkey and the Aegean Sea. Sn is efficient in parts of southwestern Turkey, the western Pontides, and western Greece. Sn is not observed in eastern Turkey and along the Aegean volcanic arc. Lg propagates efficiently in the Arabian plate including paths that cross the Dead Sea fault zone and in northwestern Turkey. Lg does not propagation in northeast Anatolia, across the Lesser Caucasus, and north of the Hellenic arc (Sea of Crete). These results are a major improvement on prior attenuation studies in this region and provide new constraints for proposed tectonic models.

title: Characterization of Biogas from Anaerobically Digested Dairy Waste for Energy Use
abstract: As the third largest dairy producer in the United States, New York is faced with the critical issue of agricultural waste management. The environmental impacts and high long-term costs of poor waste disposal have pushed the industry to realize the potential of turning this problem into an economic and sustainable initiative. The anaerobic digestion of dairy manure-derived agricultural waste produces biogas, a valuable energy resource. Anaerobic digestion offers an effective way to manage manure by addressing the principal problem of odor control while offering an opportunity to create energy from conversion of biogas with a system of combined heat and power (CHP).

Anaerobic digestion is a microbial process that produces biogas, a gas consisting of primarily methane (CH4) and carbon dioxide (CO2). The use of biogas as an energy source has numerous applications. However, all of the possible applications require knowledge about the composition and quantity of constituents in the biogas stream.

This thesis presents the findings of a study conducted over several months at five New York farms to evaluate the characteristics of dairy manure-derived biogas. Relatively long term measurements of a biogas stream at Dairy Development International (DDI) provided information about the composition and quantity of the constituents of biogas over time (day, week, months). At DDI, methane averaged 60.3% (+/-1%) of the total gas composition with an average BTU per standard cubic foot of 612 (+/-12 BTU/SCF). Carbon dioxide averaged 38.2% (+/-1%) during this period with nitrogen at 1.52% (+/-1.1%). Hydrogen sulfide, a particularly hazardous component of biogas affecting the ultimate end use of biogas in energy generation technologies measured an average of 1984 ppm (+/-570 ppm) at DDI where measurements were taken about every 3 hours over numerous 24 hour periods from July to November 2003. Biogas samples at the other four dairies illustrated rather wide variations in hydrogen sulfide concentrations from about 600 ppm to over 7000 ppm. It is suggested that the lower H2S concentrations may be due to additions of food waste to the anaerobic digester at the dairy with the low H2S concentration. The high H2S concentrations measured at another dairy are believed to be related to the significantly higher concentrations of sulfur in the farm water. For dairies not adding food wastes and not having high sulfur content in the farm water, the H2S concentrations ranged between approximately 1000 and 3600 ppm.

Water, waste and feed samples were also collected from the five dairies to determine whether the digester inputs had an effect on the components of the biogas as well as to explore the range in biogas quality at various dairies in the region. Based on the preliminary results shown in this study, it is suspected that higher sulfur contents present in feed water may have an impact on the hydrogen sulfide content in biogas generated through the anaerobic digestion of dairy manure.

These results agree with often well-quoted generalized concentrations of approximately 60% CH4, 40% CO2 and 600 BTU/SCF for dairy-derived biogas. The data also show that the H2S concentration can vary significantly depending on the type of additives in the diet and the quality of the farm water, anywhere from 600 ppm to 7000 ppm.New York State Energy Research and Development Authority (NYSERDA Agreement No.7250)

title: Seismic event location using the Eastern Turkey Seismic Network: Analysis of the Agri Dam explosion
abstract: Copyright 2004, Seismological Society of America. See also: http://www.seismosoc.org/publications/bssa-toc.html; http://atlas.geo.cornell.edu/turkey/publications/Gurbuz-et-al_2004.htmA 12 ton controlled source explosion took place in eastern Turkey on June 5, 2001 and was recorded by 18 stations of the Eastern Turkey Seismic Experiment (ETSE) PASSCAL broadband network. This is a unique recording obtained for the first time in this region. Due to the blasting type and extremely high Lg and Sn attenuation in eastern Turkey, the blast is only observed out to a distance of about 300 km. We have used travel time data from this explosion to obtain average crustal structure and site correction terms for the stations. The explosion was located using two new regional velocity models and the IASP91 velocity model to test the location capabilities of the ETSE network. We found that for surface focus events, the ETSE network is able to locate events to within 1 - 2 km of the true epicenter.

title: Contribution to the seismotectonics of eastern Turkey from moderate and small size events
abstract: An edited version of this paper was published by the American Geophysical Union (AGU). Copyright 2003, AGU. See also: http://www.agu.org/pubs/crossref/2003.../2003GL018258.shtml; http://atlas.geo.cornell.edu/turkey/publications/Orgulu-et-al_2003.htmSource properties of small-to-moderate magnitude events in eastern Turkey were studied using high quality waveform data produced by the Eastern Turkey Seismic Experiment (ETSE). A data set of fault plane solutions was obtained for 134 earthquakes using the regional moment tensor inversion technique for 34 events with magnitude 3.7 and above, and first motion analysis for 115 earthquakes with magnitude 3.0 and higher (for 15 events both techniques were used). Most of the events studied had strike slip mechanisms in agreement with nearby local fault structures. Reverse mechanisms were more scarce and were restricted to certain areas, such as in the eastern Anatolian plateau and southwest of the Karliova junction along the Arabian plate boundary. Our results indicate a difference in the deformational style east and west of the Karliova junction which results in internal deformation in the east and westward extrusion of the Anatolian plate with no or very little internal deformation in the west. Our results also suggest that in eastern Turkey, most of the collision is taken up by strike slip faults of varying types and sizes, suggesting that the northward convergence of Arabia is being accommodated by escape tectonics. Compressive features, such as thrust faulting, which were obviously the primary faulting during the earliest stages of continental collision, are still active but are of lesser importance.

title: Shear wave splitting in a young continent-continent collision: An example from eastern Turkey
abstract: An edited version of this paper was published by the American Geophysical Union (AGU). Copyright 2003, AGU. See also: http://www.agu.org/pubs/crossref/2003.../2003GL017390.shtml; http://atlas.geo.cornell.edu/turkey/publications/Sandvol-et-al_2003b.htmWe have determined the shear wave splitting fast polarization direction and delay time using data from the ETSE broadband experiment (Eastern Turkey Seismic Experiment), a deployment of 29 broadband seismic stations across the collision zone of the Arabian, Eurasian, and Anatolian plates. Our results show that the fast polarization directions are relatively uniform and they exhibit primarily NE-SW orientations. No abrupt changes in anisotropy directions are observed across the main tectonic units in the region: the Bitlis Suture (BS) and the North and Eastern Anatolian Fault zones. The fast polarization directions are determined to be sub-parallel to the Anatolian, Arabian, and Eurasian absolute plate velocities, except for those stations in the northeastern corner of the Anatolian Plateau. Observed delay times range from 0.7 to 2.0 seconds with an average value of 1.0 second; the largest values are within the northern Anatolian Plateau which is underlain by an exceptionally low velocity zone in the uppermost mantle. We interpret shear wave splitting as the vector difference of the Eurasian lithosphere and northeastern or southwestern directed flow of the asthenospheric mantle. Comparisons of the polarization anisotropy with measurements of Pn azimuthal anisotropy suggest vertical anisotropic layering except in those areas which are underlain by partially molten uppermost mantle.

title: Seismogenic zones in eastern Turkey
abstract: An edited version of this paper was published by the American Geophysical Union (AGU). Copyright 2003, AGU. See also: http://www.agu.org/pubs/crossref/2003.../2003GL018023.shtml; http://atlas.geo.cornell.edu/turkey/publications/Turkelli-et-al_2003.htmA 29-station temporary broadband PASSCAL network was operated from late October 1999 to August 2001 in eastern Turkey in order to decipher the geodynamics of one of the youngest continent-continent collision zones in the world. This paper focuses on the hypocentral distribution of local earthquakes located during the operation of the network and provides new insights into the active faulting in the Anatolian plateau. A total of 1165 earthquakes were located and classified into four different categories based on the reliability of the locations as established by the data coverage. The accuracy of the locations ranked in the best two categories is estimated to be less than approximately 5 km. The results show that seismic activity in Eastern Turkey is higher than previously documented and there were no subcrustal earthquakes beneath the Arabian- Eurasian collision zone or beneath the Anatolian plateau during our deployment. This result suggests no or very little underthrusting of the Arabian plate beneath Eurasia. Our results also suggest that the North Anatolian Fault zone extends farther toward the southeast, well beyond the Karliova triple junction, and that a number of unmapped active, seismogenic faults exist in the region. We also observed a possible difference in the seismogenic thickness of the East Anatolian fault zone (EAFZ) and the North Anatolian fault zone (NAFZ).

title: The crustal structure of the East Anatolian plateau (Turkey) from receiver functions
abstract: An edited version of this paper was published by the American Geophysical Union (AGU). Copyright

2003, AGU. See also: http://www.agu.org/pubs/crossref/2003.../2003GL018192.shtml; http://atlas.geo.cornell.edu/turkey/publications/Zor-et-al_2003.htmThe crustal structure of the Anatolian plateau in Eastern Turkey is investigated using receiver functions obtained from the teleseismic recordings of a 29 broadband PASSCAL temporary network, i.e., the Eastern Turkey Seismic Experiment [ETSE]. The S-wave velocity structure was estimated from the stacked receiver functions by performing a 6-plane layered grid search scheme in order to model the first order features in the receiver functions with minimum trade-off. We found no significant crustal root beneath the western portion of the network, but there is some evidence of crustal thickening in the northern portion of the network. We found an average crustal thickness of 45 km and an average crustal shear velocity of 3.7 km/s for the entire eastern Anatolian plateau. Within the Anatolian plateau we found evidence of a prominent low velocity zone where the crust thickness is approximately 46 km. These results suggests that the 2 km high topography across the Anatolian plateau is dynamically supported because most of the plateau appears to be isostatically under-compensated. Also, there appears to be a region of thin crust at the easternmost edge of the Anatolian plateau that may be a relic from the accretion of island arcs to the Eurasian plate.

title: EXEGI MONUMENTUM: ARCHITECTURE IN LATIN EPIC
abstract: For the poets of the early empire, architecture and architectural imagery was an important medium through which to explore the relationship between political power and poetic art. Virgil and Horace, and their contemporaries and successors, composed literary monuments to stand beside the physical monuments of their patrons. No less than the palaces and temples of the emperors, these literary monuments participated in the formulation and evolution of imperial ideology. Within those poetic monuments, the description of architecture afforded a space in which to explore the relationship between poetry, monumental and pictorial art, and political power. This study is an attempt to elucidate how Virgil and his successors explore the dynamics of this relationship.

title: INCUBATING FOR INTELLIGENCE: SPATIAL ATTRIBUTES AND INTERACTION EMERGENCE IN CORPORATE WORKPLACE
abstract: As industries increasingly rely on innovation and knowledge workers, interaction and social networks have once again emerged as a primary purpose for working together in the place called office. The purposes of this thesis are (1) to investigate the roles of physical setting, especially on building and site scale, and its influence to foster communication and interaction in large organizations, and (2) to explore analytical tools and techniques to verify the performance of workplace spatial attributes and interaction patterns.
Employing the archival data of interaction patterns and physical data acquired from satellite images and GIS, This thesis investigates the relationship between spatial attributes and interaction emerged in four corporate campuses, including Goldman Sachs, Sprint, Sun Microsystems, and Toyota Motor Sale.
The analysis reveals that there are very low correlations for both relationships between floor plate area and interaction, and relationships between floor plate ratio and interaction. In addition, there is no predictable trend between the average travel time between building and the average interaction frequency.
There is a moderate correlation between actual travel time and self-reported or perceived travel time. The thesis also suggests that the self-reported travel time tends to be under-estimated by the employees. The actual

travel time, however, has more impact on interaction in compact campuses than in dispersed campuses.

title: East Anatolian high plateau as a mantle supported, north-south shortened domal structure
abstract: An edited version of this paper was published by the American Geophysical Union (AGU). Copyright 2003, AGU. See also: http://www.agu.org/pubs/crossref/2003.../2003GL017858.shtml; http://atlas.geo.cornell.edu/turkey/publications/Sengor-et-al_2003.htmThe East Anatolian High Plateau is a region of average ~2 km elevation a.s.l. exhibiting active diffuse N-S shortening and widespread Pliocene to recent volcanicity. Its elevation was hitherto thought to result from a presumed crustal thickness of +/- 55 km. Seismic data collected by a new network of 29 seismograph stations have shown, however, that its crustal thickness is only some 45 km. Combined with observations on Pn and Sn phases, this shows that most of the East Anatolian High Plateau is devoid of mantle lithosphere. Areas of no mantle lithosphere are inferred to coincide broadly with the extent of the East Anatolian Accretionary Complex, a subduction-accretion prism of late Cretaceous to earliest Oligocene age. The absence of mantle lithosphere is ascribed to breakoff of northward subducted slab beneath the prism and the widespread vulcanicity to melting its lower levels because of direct contact with hot asthenosphere The East Anatolian High Plateau is thus supported not by thick crust, but by hot mantle.

title: Northern Arabian platform transect across the Palmyride mountain belt, Syrian Arab Republic, Global Geoscience Transect 1
abstract: An edited version of this paper was published by the Inter-Union Commission on the Lithosphere and the American Geophysical Union, and copyright is retained by these publishers. See also: http://atlas.geo.cornell.edu/syria/Al-Saad-et-al_1991.htmlThis transect traverses central Syria for approximately 450 km from the Iraqi border in the southeast to the Turkish border in the northwest (see transect location map and appendix note 1) and is one of three transects that represent the Syrian Arab Republic's contribution to the Global Geoscience Transects (GGT) Project. Syria is located on the northern portion of the Arabian platform, which is surrounded by major active tectonic systems: the Zagros belt to the east and northeast, the East Anatolian and Bitlis suture to the north, and the Dead Sea transform fault system along the Levantine margin to the west. More than 2000 km of industry seismic reflection data linked by nine exploration wells and surface geologic maps provide a detailed image of subsurface structure to about 10 km depth along the transect, and when combined with two-dimensional modeling of the gravity and magnetic data, make it possible to construct a complete geological cross section through the entire crust.
Three major tectonic provinces of central Syria are crossed by the transect from south to north: the Rutbah uplift, the intraplate Palmyride mountain belt, and the Aleppo plateau.

The Rutbah uplift is a broad, domal basement-cored feature located on the stable northern Arabian platform and is the northernmost part of a larger uplift centered in Iraq. Isopach maps indicate that the Rutbah uplift region was an Early Paleozoic depocenter that collected approximately 6-7 km of Phanerozoic, mostly Paleozoic, sediments.

The Palmyride fold belt forms a northeast-southwest trending intracratonic mountain belt, representing the Late Mesozoic and Cenozoic inversion of an Early Mesozoic failed rift. The Palmyrides act as a mobile tectonic zone between the relatively stable Rutbah uplift and the less stable Aleppo plateau. A system of en echelon faults and broad folds characterize the northeast region, while short wavelength folds, generally with relatively steep, southeast faulted flanks dominate in the southwest.

The Aleppo plateau lies immediately north of the Palmyrides. Its sedimentary section is generally 4-5 km thick and is composed of both Paleozoic and Mesozoic strata. Although this region appears relatively undeformed on seismic reflection data, a system of northeast-southwest trending, near vertical faults with probable strike-slip motion crosscut the region.

Two-dimensional gravity modeling indicates that the northern Arabian platform beneath Syria may have an early tectonic history similar to the exposed Arabian shield to the south in Jordan and in Saudi Arabia, marked by Proterozoic convergence and Early Cambrian rifting. Mesozoic rifting and Cenozoic transpression in Syria are linked to later plate interactions with the Eurasian plate in the north and east and to the opening of the Red Sea.

The GGT transects in Syria provide new comprehensive Phanerozoic stratigraphic cross sections and estimates of crustal architecture that detail the structural and stratigraphic history of the northern Arabian platform beneath Syria. Major active tectonic systems outline the boundaries of the Arabian plate on its northern flank: the Dead Sea transform fault system along the Levantine margin to the west, the East Anatolian fault system and Bitlis suture to the north, and the Zagros suture and fold belt to the east and northeast. Each of these systems has contributed to the development of the Cenozoic tectonic framework of Syria.

The database for this transect includes detailed geologic maps (appendix note 2), a composite seismic profile consisting of eight seismic reflection lines, information from nine exploratory wells (ranging in depth from 2 to 4 km), and Bouguer gravity (appendix note 3) and aeromagnetic (appendix note 4) data. The 450-km seismic transect includes information from an additional 1500 km of seismic reflection data forming cross lines and nearby parallel lines within a 100-km swath along the transect.

title: Crustal structure of central Syria: The intracontinental Palmyride Mountain belt
abstract: An edited version of this paper was published in Tectonophysics by Elsevier Science. Copyright 1992, Elsevier Science. See also: http://dx.doi.org/10.1016/0040-1951(92)90395-M; http://atlas.geo.cornell.edu/syria/Al-Saad-et-al_1992.htmlAlong a 450 km transect across central Syria seismic reflection data, borehole information, potential field data and surface geologic mapping have been combined to examine the crustal structure of the northern Arabian platform beneath Syria. The transect is surrounded by the major plate boundaries of the Middle East, including the Dead Sea transform fault system along the Levantine margin to the west, the Bitlis suture and East Anatolian fault to the north, and the Zagros collisional belt to the northeast and east. Three main tectonic provinces of the northern Arabian platform in Syria are crossed by this transect from south to north: the Rutbah uplift, the Palmyra fold-thrust belt, and the Aleppo plateau. The Rutbah uplift in southern Syria is a broad, domal basement-cored structure with a thick Phanerozoic (mostly Paleozoic) cover of 6-7 km. Isopachs based on well and seismic reflection data indicate that this region was an early Paleozoic depocenter. The Palmyra fold-thrust belt, the northeastern arm of the Syrian Arc, is a northeast- southwest trending intracontinental mountain belt that acts as a mobile tectonic zone

between the relatively stable Rutbah uplift to the south and the less stable Aleppo plateau to the north. Short wavelength en echelon folds characterized by relatively steep, faulted southeast flanks dominate in the southwest, most strongly deformed segment of the belt, while a complex system of deeply rooted faults and broad folds characterize the northeast region, described in this study. The Aleppo plateau lies immediately north of the Palmyride belt, with a combined Paleozoic and Mesozoic sedimentary section that averages 4-5 km in thickness. Although this region appears relatively undeformed on seismic reflection data when compared to Palmyride deformation, a system of near vertical, probable strike-slip faults crosscut the region in a dominantly northeasterly direction.

Gravity and magnetic modeling constrains the deep crustal structure along the transect. The crustal thickness is estimated to be approximately 38 km. Interpretation of the gravity data indicates two different crustal blocks beneath the Rutbah uplift and the Aleppo plateau, and the presence of a crustal-penetrating, high-density body beneath the northeast Palmyrides. The two distinct crustal blocks suggest that they were accreted possibly along a suture zone and/or a major strike-slip fault zone located approximately in the present-day position of the Palmyrides. The age of the accretion is estimated to be Proterozoic or early Cambrian, based on the observation of a pervasive reflection (interpreted as the Middle Cambrian Burj limestone) in the Rutbah uplift and in the Aleppo plateau and by analogy with the well-mapped Proterozoic sutures of the Arabian shield to the south.

title: The intraplate Euphrates fault system - Palmyrides mountain belt junction and relationship to Arabian plate boundary tectonics
abstract: This paper was published in Annali di Geofisica by Editrice Compositori. Copyright 1995, Editrice Compositori. See also: http://www.ingv.it/~wwwannali/alsdorf383.htm; http://atlas.geo.cornell.edu/syria/alsdorf-et-al-1995.htmlBased on an extensive, recently released dataset of seismic reflection profiles and well logs, we document and map a northwest-southeast oriented graben of about 20 km width located beneath the Euphrates depression in central Syria. The uppermost Cretaceous age of this graben is contemporaneous with the first phase of inversion and uplift along the adjacent Palmyride mountain belt. We interpret both of these intraplate structures, the Euphrates graben and the Palmyride mountains, to have developed in direct response to a major episode of convergence and continental collision that started in the uppermost Cretaceous time along the nearby Arabian plate boundaries, i.e., the Bitlis and Zagros sutures. Kinematic considerations suggest that the Euphrates graben formed as a tear in the Arabian crust. During the Cenozoic, the intense mountain building processes along the Palmyrides contrast with the persistent broad depression along the Euphrates and most of eastern Syria. We map a series of strike-slip faults that separate the Palmyrides from the Euphrates and appear to decouple these adjacent structures. The broad depression may be related to the Mesopotamian foredeep that developed in response to the nearby Zagros continental collision zone.

title: EFFECTS OF A VIBRATING MOUSE ON COMPUTER USERS' WORK BEHAVIOR AND PERFORMANCE
abstract: Alan Hedge, Jeffrey HancockFrequent brief rest breaks, known as micro-breaks, have been shown to benefit computer users by reducing fatigue and possibly preventing musculoskeletal disorders. Various methods of reminding users to take rest breaks have been developed. Initially, efforts focused on the use

of break reminder computer software, although potentially this may be disruptive to work patterns. More recently, micro-break reminders have been incorporated into computer equipment and these have been indexed to work activity, and this approach may offer less potential for disrupting work activities.

A computer mouse has been developed that vibrates in the user's hand after 10 seconds of inactivity. The vibration is intended to remind the user to rest his or her hand in a neutral position while not actively engaging the mouse rather than maintaining a grip on the mouse that requires static muscle contraction.

A laboratory experiment was conducted to test this vibrating mouse against a conventional mouse to see how it affected subjects' task performance, task behaviors, and mouse preference. It was hypothesized that the vibrating mouse would increase the number of times subjects removed their hands from the mouse, be minimally disruptive and have no adverse effect on task performance. The study also explored what subjects did with their hand when this was removed from the mouse.

Eleven female and seven male subjects participated in the experiment. Use of the vibrating mouse (experimental condition) was compared to use of a conventional mouse (control condition) for five consecutive tasks. The first three tasks required the finding and correcting of duplicate words, the finding and correcting of duplicate sentences and the finding and correcting of misspelled words from text passages. The final two tasks were a reading comprehension task, where the subjects answered four multiple-choice questions about a text passage, and a composition task in response to a business scenario.

Subjects were videotaped to collect data on their behavior while completing the tasks under both conditions. Task time and number of errors were collected as performance measures. User preferences and musculoskeletal discomfort were gathered using two questionnaires, one administered pre test and one post test.

No differences were found in performance between the two conditions. The vibrating mouse induced more positive task behaviors than the conventional mouse, including significantly more resting behavior ($p=0.02$) and slightly more hand removals ($p=0.06$). The vibrating mouse, however, also induced significantly more negative task behaviors than the conventional mouse, such as increasing the frequency of unsupported hand hovering ($p=0.00$).

Nine subjects found that the vibrating mouse was disruptive to their performance during the duplicate word and reading tasks; and eight found that the vibrating mouse was disruptive during the duplicate word task. The effectiveness of the mouse seemed to correspond to task type and also to subjects' mouse use technique.

Because of technological limitations and a desire to limit extraneous distractions to the subjects during the tasks, the vibration occurrence data was collected by subjects' self reporting the number of vibration occurrences they experienced. This subjectiveness may have compromised the reliability of the vibration frequency data.

The vibrating mouse shows promise but more research is needed to understand the conditions under which a vibration occurs and therefore when a user would gain benefits from this mouse. The effects of task type and user technique need to be examined in more detail to determine the nature of these effects before recommendations can be made as to the proper implementation of the vibrating mouse.College of Human Ecology

title: Adventures in Pattern Formation: Spatially Periodic Forcing and Self-Organization
abstract: This dissertation describes an experimental exploration of pattern formation in a convecting fluid subjected to spatially-periodic forcing. The flow is driven thermally in a high-precision compressed gas apparatus and visualized using shadowgraphy. The forcing is introduced by microfabricating a regular pattern of polymer ridges on the lower boundary of the convection cell. We frustrate the system by choosing a forcing wavelength which lies outside of the balloon of periodicities for which unforced flow patterns are

stable. This arrangement, even for polymer ridge heights much less than the thickness of the fluid layer, has dramatic and unexpected consequences for the system?s pattern-forming dynamics.
Available theoretical work on spatially periodic forcing of thermal convection is applicable only close to onset. We rederive an important qualitative prediction that, due to the forcing, there should be convection present for all applied temperature differences. Quantitative comparisons with experimental data confirm that this theory correctly describes the physics of the spatially forced patterns near the threshold defined by the onset of convection in the unforced system.
Near the critical point, the pattern is phase-locked to the forcing and stationary. At larger applied temperature differences, we find a wealth of complex dynamical phenomena. In particular, where the pattern starts to break free of the forcing, we observe a completely new and unexpected phenomenon: the pattern uses mobile, highly localized structures to reassert its preferred periodicities. In this regime, the dynamics blend spatiotemporal chaos with the self-organization of robust, localized crystalline structures. We use a variety of techniques inspired by condensed matter physics, nonlinear systems, and pattern formation to characterize this remarkable twist on the classic theme of order within chaos. Then, reinterpreting these ?crystalline chaotic? dynamics as an intermediate phase mediating the emergence of spiral defect chaos in the spatially forced environment, we give a more complete tour of the phase space, placing special emphasis on localized structure formation, on the secondary instability of the phase-locked pattern, and on resonance structures in the chaotic patterns.National Science Foundation, Cornell IGERT Nonlinear Science Program, Cornell NanoScale Facility, Cornell Nanobiotechnology Center

title: Tectonic evolution of the northern Arabian plate in western Syria
abstract: This paper was published in the volume Recent Evolution and Seismicity of the Mediterranean Region published by Kluwer Academic Publishers. Kluwer Academic Publishers retains the copyright to this paper. See also: http://atlas.geo.cornell.edu/syria/barazangi-et-al-1993.htmlThe primary geologic structures of the northern Arabian plate in western Syria include the intracontinental Palmyride mountain belt and the interplate boundary of the Dead Sea transform fault system. The Palmyride belt strikes NE and is sandwiched between two relatively stable crustal blocks of the Arabian platform: the Aleppo plateau in the north and the Rutbah uplift in the south. The Palmyrides were the site of an early Mesozoic aulacogen-type depression that was linked to the Levantine rifted continental margin in the eastern Mediterranean. The location of this postulated aulacogen may be genetically associated with a crustal zone of weakness, possibly a Proterozoic suture and/or shear zone, between the Aleppo and Rutbah crustal blocks. Uplift of the intraplate Palmyride depression initiated in the Late Cretaceous, penecontemporaneous with emplacement of ophiolites along the nearby Arabian plate boundaries in southern Turkey and western Iran. More intense episodes of shortening during the Cenozoic also appear to be temporally related to collision along nearby plate boundaries, implying that stresses have been transmitted hundreds of kilometers across the northern Arabian platform. The style and intensity of the inversion process vary considerably along the strike of the Palmyrides and involves both shortening by folding and reverse faulting as well as translation and rotation along numerous strike-slip faults. Such folds and faults clearly define at least three structurally distinct small crustal blocks within the Palmyrides. Shortening of about 20% in the southwest Palmyrides near Lebanon gradually dies out to the northeast near the intersection of the Palmyrides with the NW-trending Euphrates depression. Depth to metamorphic basement beneath the Palmyra mountain belt increases from 9 km in the northeast to 11 km in the southwest, compared with a basement depth of about 6-8 km in the adjacent Arabian platform, indicating that shortening along the Palmyrides has been insufficient to invert the previously extended basement morphology. Finally, slip measurements along the Dead Sea fault and estimates of crustal shortening in the

Palmyride belt indicate that the northern segment of the seismogenic active Dead Sea fault in Lebanon and Syria is considerably younger (Pliocene) than the southern part (Miocene).

title: Structure of the intracontinental Palmyride mountain belt in Syria and its relationship to nearby Arabian plate boundaries
abstract: Copyright 1992, Cukurova University. See also: http://atlas.geo.cornell.edu/syria/barazangi_1992.htmThe intracontinental Palmyride mountain belt strikes NE and is located within the northern Arabian platform. The belt is about 400 km in length and about 100 km in width. Abundant data, including seismic reflection and refraction profiles, drill holes, gravity, magnetics, and geologic maps are used to infer the crustal structure and geologic evolution of this belt.

The Palmyrides were the site of an early Mesozoic aulacogen-type depression that was linked to the Levantine rifted continental margin in the eastern Mediterranean. Seismic stratigraphic analysis indicates that inversion of the Palmyride depression was initiated in late Cretaceous time, but especially intensified in Neogene and Quaternary times. The inversion process varies considerably along strike and involves both shortening by folding and reverse faulting (including the inversion of some of the Mesozoic rift-bounding normal faults) as well as translation and rotation along numerous strike-slip faults. The inversion processes formed at least three structurally distinct crustal blocks within the Palmyrides. The two blocks in the northeast Palmyrides (Bilas and Bishri) consist of broad anticlines that exhibit symmetrical thick-skinned deformation with reverse faults on the southern and northern flanks of the belt, whereas the southwestern Palmyrides consist of long linear ridges with intervening depressions that exhibit clear south vergence and local detachment, probably within Triassic evaporites. Depth to metamorphic basement beneath the Palmyrides increases from 9 km in the northeast to 11 km in the southwest. This is in contrast to a basement depth of about 6-8 km beneath the adjacent stable Arabian platform. A 20-25% estimated shortening across the southwestern Palmyrides has not been sufficient to invert the basement morphology beneath this mountain belt.

Close temporal relations between inversion episodes in the Palmyrides and well-documented episodes of convergence and collision along nearby Arabian plate boundaries suggest that plate boundary stresses are transmitted hundreds of kilometers across the northern Arabian platform to the Palmyrides. Finally, Bouguer gravity observations provide an estimate of crustal thickness of about 38 km beneath the Palmyrides, but also require different crustal properties to the north and south of the Palmyrides. These observations suggest that the Palmyrides occupy the location of a possible Precambrian (Proterozoic?) suture and/or strike-slip fault zone along which the two crustal blocks of northern Arabia were accreted. This possible early history may explain the subsequent development of the Palmyrides in early Mesozoic time as due to a reactivation of a zone of crustal weakness along the postulated Proterozoic suture zone.

title: Continental margin evolution of the northern Arabian platform in Syria
abstract: Copyright AAPG 1993, reprinted by permission of the AAPG whose permission is required for further use. See also: http://atlas.geo.cornell.edu/syria/best_1993.htmlSynthesis of available geological and geophysical data in the Syrian Arab Republic permits a descriptive account of the pre-Cenozoic geologic history of the northern Arabian platform. The northern Arabian platform appears to be a composite plate similar to that interpreted in the rocks of the Arabian shield. The structural and stratigraphic relationships

of the Paleozoic and Mesozoic sedimentary sections in Syria record the transformation of an east-facing Gondwanaland passive-margin in the early Paleozoic into a west-facing Levantine margin in the Mesozoic, at which time the northern platform was intimately associated with the creation of the eastern Mediterranean basin. Timing of the margin transformation is inferred from the orientation and thickness variations of Lower Triassic rocks, but the transformation may have initiated as early as the Permian. The diversity and timing of geologic features in Syria suggest that the northern Arabian platform did not behave as a rigid plate throughout its geologic history. The present-day Palmyride mountain belt located within the northern Arabian platform in Syria, initiated in early Mesozoic time as a northeast trending rift nearly perpendicular to the Levantine margin, was subsequently inverted in the Cenozoic by transpression. The location of the rift may be associated with the reactivation of a zone of crustal weakness, i.e., a Proterozoic suture zone previously proposed from modeling of Bouguer gravity data. Thus, the northern and southern portions of the Arabian platform have similarities in their geologic history during the Proterozoic and Paleozoic; however, the northern Arabian platform was intimately affected by Mesozoic rifting and the creation of the eastern Mediterranean basin during the Mesozoic.

title: Bouguer gravity trends and crustal structure of the Palmyride mountain belt and surrounding northern Arabian platform in Syria
abstract: Copyright 1990, Geological Society of America. See also: http://dx.doi.org/10.1130%2F0091-7613%281990%29018%3C1235%3ABGTACS%3E2.3.CO%3B2 http://atlas.geo.cornell.edu/syria/best_1990.htmlThis study examines the crustal structure of the Palmyrides and the northern Arabian platform in Syria by two- and three-dimensional modeling of the Bouguer gravity anomalies. Results of the gravity modeling indicate that: (1) western Syria is composed of at least two different crustal blocks, (2) the southern crustal block is penetrated by a series of crustal-scale, high-density intrusive complexes, and (3) short-wavelength gravity anomalies in the southwest part of the mountain belt are clearly related to basement structure. The crustal thickness in Syria, as modeled on the gravity profiles, is approximately 40 +/- 4 km, which is similar to crustal thicknesses interpreted from refraction data in Jordan and Saudi Arabia. The different crustal blocks and large-scale mafic intrusions are best explained, though not uniquely, by Proterozoic convergence and suturing and early Paleozoic rifting, as interpreted in the exposed rocks of the Arabian shield. These two processes, combined with documented Mesozoic rifting and Cenozoic transpression, comprise the crustal evolution of the northern Arabian platform beneath Syria.

title: Tectonic evolution of the northeast Palmyride mountain belt, Syria: the Bishri crustal block
abstract: This material has been published in The Journal of the Geological Society, London 160, 677-685, 2003, the only definitive repository of the content that has been certified and accepted after peer review. Copyright and all rights therein are retained by the Geological Society of London. See also: http://www.geolsoc.org.uk/template.cfm?name=Journals_JGS_home_page; http://atlas.geo.cornell.edu/syria/brew_jgs_2003.htmlInvestigating the Bishri block, centrally positioned amid the diverse tectonic and structural zones of Syria, reveals details of the intraplate Phanerozoic development of the northern Arabian platform. The Bishri block is a broad northeast plunging inverted basin located at the northeast portion of the Palmyride mountain belt where the mountains intersect the Euphrates fault system. Well and seismic data show that subsidence

and sedimentation in the Bishri area was generally continuous from Carboniferous to Palaeocene time, with the Bishri block part of the extensive Palmyride / Sinjar trough. Major bounding faults and a rift-type environment are documented in the Permo-Triassic, Jurassic and Cretaceous. The present Bishri structural and topographic high has been formed through transpressive structural inversion since the Middle Miocene; high-angle Mesozoic bounding normal faults now have net reverse offsets with a significant dextral strike-slip component. East of the Bishri block, towards the Euphrates fault system, north-northwest - south-southeast striking normal faults exhibit less reverse movement. This deformation history correlates with the opening and closing of the nearby NeoTethys ocean that has driven the evolution of the intracontinental Syria.

title: Tectonic evolution of Syria Interpreted from Integrated Geophysical and Geological Analysis
abstract: Copyright 2001, Graham Brew. See also: http://atlas.geo.cornell.edu/syria/brew_dissertation2001.htmUsing a variety of geophysical and geological data, the Phanerozoic tectonic evolution of Syria has been interpreted. The study is inspired by the diverse styles of tectonic deformation within Syria generated by long-lived proximity to active plate boundaries. The work is also relevant to hydrocarbon exploration. The availability of seismic reflection and refraction profiles, wells, and other resources made this research possible. Three studies focused on specific areas of Syria are presented. The first is a seismic refraction interpretation along a north-south profile in eastern Syria. The results show that metamorphic basement depth (and hence Paleozoic thickness) in southeast Syria is greater, by >2 km, than that in the northeast.
The next study interprets the structure and tectonics in northeast Syria. During Late Paleozoic and Mesozoic time northeast Syria was an extension of the Palmyride trough. In the Maastrichtian, regional extension opened the Abd el Aziz and Sinjar graben that were structurally inverted in the Late Cenozoic to form the present topography. The third study concerns the Ghab Basin in western Syria. This 3.4 km deep Plio-Quaternary pull-apart basin suggests that the Dead Sea Fault System has only been active in Syria since the end of the Miocene in accordance with a two-phase model of Red Sea opening.
The final study integrates the previous interpretations with new work to provide a tectonic evolutionary model that shows the Phanerozoic development of all Syria. This model is closely tied to stratigraphic data that improve the interpretation of many tectonic events, and put the results into a paleogeographical context. The model shows how specific deformation episodes within Syria have been penecontemporaneous with regional plate tectonic events. The Late Paleozoic / Mesozoic northeast trending Palmyride / Sinjar trough formed across central Syria in response to Permo-Triassic opening of the NeoTethys Ocean. Proximal subduction in the NeoTethys created the Late Cretaceous Euphrates Fault System and Abd El Aziz / Sinjar graben in eastern Syria. Late Cretaceous to Late Miocene collisions and shortening along the northern Arabian margin caused platform-wide structural inversion, uplift, and shortening. This compression continues today under the influence of Arabia / Eurasia convergence.

title: Tectonic map and geologic evolution of Syria: The role of GIS
abstract: This paper was published in the journal The Leading Edge by the Society of Exploration Geophysicists. SEG retains the copyright to this paper. See also: http://www.edge-online.org/; http://atlas.geo.cornell.edu/syria/brew_tle_2000.htmlFor the past 12 years, Cornell Syria Project scientists and colleagues at the Syrian Petroleum Company have studied the regional structure and geologic evolution of Syria. We are currently generating new structural maps and tectonic models for the whole country. Information on this region is relatively limited, despite the local importance of hydrocarbon production and abundant surface and subsurface data. Our regional approach involves new interpretations of seismic reflection profiles, well data, remote sensing imagery, and potential-field data, merged with existing interpretations of similar data sets. These interpretations, integrations, analyses, and map preparation are all performed within a GIs platform. As detailed elsewhere in this issue, the importance of GIs as a data storage and interrogation tool for petroleum exploration is well established. This article describes our use of GIs to facilitate regional tectonic mapping in Syria. Although not directly related to the search for hydrocarbons, the maps and models generated have obvious utility for oil exploration. Herein we detail the types of data being used, their integration and interpretation within the GIs, and our preliminary analysis and findings. We will show how a GIs approach eases data archiving and map generation and also provides interpretational possibilities not available with more traditional mapping procedures.

title: Basement depth and sedimentary velocity structure in the northern Arabian platform, Eastern Syria

abstract: An edited version of this paper was published in Geophysical Journal International by Blackwell Publishing. Blackwell Publishing retains the copyright. See also: http://www.blackwellpublishing.com/journal.asp?ref=0956-540X&site=1; http://atlas.geo.cornell.edu/syria/brew_gji_1997.htmBasement depth in the Arabian plate beneath eastern Syria is found to be much deeper than previously supposed. Deep-seated faulting in the Euphrates graben system is also documented. Data from a detailed, 300 km long, reversed refraction profile, with offsets up to 54 km, are analyzed and interpreted, yielding a velocity model for the upper ~ 9 km of continental crust. The interpretation integrates the refraction data with seismic reflection profiles, well logs and potential field data, such that the results are consistent with all available information. A model of sedimentary thicknesses and seismic velocities throughout the region is established. Basement depth on the north side of the Euphrates is interpreted to be around 6 km, whilst south of the Euphrates basement depth is at least 8.5 km. Consequently, the potentially hydrocarbon-rich pre-Mesozoic section is shown, in places, to be at least 7 km thick. The dramatic difference in basement depth on adjacent sides of the Euphrates graben system might suggest that the Euphrates is a suture zone, possibly inherited from Late Proterozoic accretion of the Arabian plate. Gravity modeling across the southeast Euphrates system tends to support this hypothesis. Incorporation of previous results allows us to speculate on the position of possible suture zones in Syria.

title: Summary of the geological evolution of Syria through geophysical interpretation: Implications for hydrocarbon exploration
abstract: This paper was published in the journal The Leading Edge by the Society of Exploration Geophysicists. SEG retains the copyright to this paper. See also: http://www.edge-online.org/; http://atlas.geo.cornell.edu/syria/brew_tle_1997.htmlIntracontinental deformation, caused by plate boundary processes, dominates the past and present tectonics of Syria (Figure 1). This deformation has created structures that form hydrocarbon traps in several different areas of the country. Current production from Syria is around 600,000 barrels per day and the country hosts ongoing exploratory efforts. Deformation within Syria can be conveniently divided into four zones (Figure 2): the Dead Sea fault system; the Palmyride fold and thrust belt; the Euphrates fault system; and the Abd el Aziz / Sinjar structures in the northeast of the country. Each of these areas have been, and continue to be, studied in detail by the Cornell Syria Project. The Syria Project is an industry sponsored collaborative program between Cornell and Syrian Petroleum Company (SPC) scientists that uses diverse geophysical and geological data to analyze the tectonics of the northern Arabian platform.

title: Crustal shortening in the Palmyride fold belt, Syria, and implications for movement along the Dead Sea fault system
abstract: An edited version of this paper was published in Tectonics by the American Geophysical Union (AGU). Copyright 1990, AGU. See also: http://www.agu.org/journals/tc/; http://atlas.geo.cornell.edu/syria/chaimov_tectonics_1990.htmlThe Palmyride fold belt is a northeast-trending, 400 by 100 km transpressive belt in central Syria embedded in the northern Arabian platform, bounded to the north by the Aleppo plateau and to the south by the Rutbah uplift. Palinspastically restored cross sections from three transects across the Palmyride fold belt demonstrate a minimum NW-SE shortening of about 20% or 20 km across the southwestern segment of the belt, diminishing to 1-2 km in the northeast, close to the Euphrates graben system.

The cross sections are based on the 1:200,000 scale geologic map of Syria and previously unavailable seismic reflection and well data, all provided by the Syrian Petroleum Company. These results differ significantly from those predicted by kinematic models of Middle East plate motions. In western Syria and eastern Lebanon the Palmyrides obliquely intersect (at about 45 degrees) the roughly north-trending Dead Sea transform fault system. The Dead Sea fault system shows well-documented evidence of 105 km of left-lateral displacement since mid-Tertiary time south of its intersection with the Palmyrides, yet only about 25 km of motion has been documented north of that juncture in Lebanon and western Syria. Thus, kinematic models of Middle East plate motions predict 80 km of shortening in Syria, most of which should be accommodated in the Palmyride fold belt. Several possibilities exist to explain the discrepancy between the 80 km of predicted shortening and the only 20 km of shortening measured from restored cross sections. Restored cross sections offer only minimum shortening estimates, so the calculated 20 km may underestimate shortening. Second, evidence of strike-slip displacement recognized in the field and reported in the literature, and indicated by new focal mechanism solutions of two recent earthquakes in the Palmyrides, indicates that some of the still "missing" displacement may be distributed throughout central and northern Syria as strike-slip motion oblique to the relative northward convergence of the Arabian plate on the Eurasian plate. Alternatively, previous estimates of slip along the northern segment of the Dead Sea transform fault system may be only minimum estimates. A final possibility is that the Dead Sea transform fault in northwestern Syria has been active for only the past 5-6 m.y. or so, implying that it was either nonexistent or moved only slightly before the Pliocene. This would suggest that there is a total of only 45 km of N-S convergence to be found in central and northern Syria, about 25 km on the Dead Sea fault system and about 20 km in the Palmyrides. This last possibility requires that the northern and southern segments of the Dead Sea fault system developed independently during most of the past 15-20 m.y. In light of the documented but unquantified strike-slip motion in the Palmyrides, it seems reasonable that strike-slip motion does accommodate a significant portion of the convergence between the Arabian and Eurasian plates. It is likely, however, that one or more of the other proposed mechanisms also accounts for a component of the expected 80 km of shortening.

title: Mesozoic and Cenozoic deformation inferred from seismic stratigraphy in the southwestern intracontinental Palmyride fold-thrust belt, Syria
abstract: This paper was published in the Geological Society of America Bulletin. The Geological Society of America retains the copyright to this paper. Geological Society of America, P.O. Box 9140 , Boulder, CO 80301-9140 USA See also: http://www.geosociety.org/; http://atlas.geo.cornell.edu/syria/chaimov_gsa_bull_1992.htmlThe Palmyride fold belt in central Syria is an intracontinental northeast-trending, 400 by 100 km transpressive belt embedded in the northern Arabian platform. During the Late Paleozoic and most of the Mesozoic the region of the present-day mountains was a rift-like trough that collected over 5 km of sediments, for a total Phanerozoic thickness of over 10 km. The southwestern sector of the fold belt is bounded in the

north by the Jhar fault and in the south by the south-vergent frontal thrust faults of the Palmyrides, with the broad Al-Daww depression in between. Structural features that characterize the southern and southwestern region of the Palmyrides include a short wavelength, typically 5-10 km, fold style controlled by a regional low-angle decollement within Triassic beds, and small inverted Jurassic and Early Cretaceous normal faults.
Small intermontane basins (about 10 X 30 km) whose strata can be used to document the history of Palmyride deformation flank growth fault-bend folds and are mainly a product of Cenozoic shortening in the belt. These structures are elucidated by about 2000 km of newly available seismic reflection data in the Palmyrides. Synthetic seismic traces generated solely from forward modeling of outcrop information constrain seismic stratigraphic picks in two small basins about 100 km northeast of Damascus. There, minor Late Cretaceous uplift caused local onlap, marking the first inversion phase of the Palmyride trough. Tectonic quiescence throughout the Paleogene, interrupted only in the Middle Eocene by minor tectonism, resulted in monotonous deposition of about 2500 m of mostly limestone. Marked onlap and probable downlap of Lower Miocene strata onto an Oligocene angular unconformity indicate accelerated tectonism by Late Oligocene to Early Miocene time. This marks the beginning of the major phase of inversion and uplift of the Palmyrides. Recent seismicity indicates that transpression continues today.
Despite its relative remoteness from convergent plate boundaries (the nearest, the Bitlis suture in southern Turkey, is about 300 km distant), the Late Cretaceous, Middle Eocene, and Neogene phases of deformation in the intraplate setting of the Palmyrides have a direct temporal relationship with major regional tectonism that occurred along the surrounding Arabian plate boundaries. The Palmyride trough was inverted in Late Cretaceous time and, subsequently, developed into a transpressive zone throughout Neogene and Quaternary times. Thus, the initiation of inversion in the Palmyrides, an integral part of the Syrian Arc, which extends from central Syria southward to central Sinai, apparently predates development of the Red Sea/Dead Sea plate boundary. In contrast, the intense Neogene through Quaternary deformational episode is clearly related to development of the Red Sea/Dead Sea fault system and to convergence along the northern boundary of the Arabian plate in southern Turkey.

title: Seismic fabric and 3-D upper crustal structure of the southwestern intracontinental Palmyride fold belt, Syria
abstract: Copyright 1993, AAPG. Reprinted by permission of the AAPG whose permission is required for further use. See also: http://aapgbull.geoscienceworld.org/; http://atlas.geo.cornell.edu/syria/chaimov_aapg_bull_1993.htmlThe Palmyride fold belt, a 400 X 100 km transpressive belt in central Syria that is the northeastern arm of the Syrian Arc, which includes the Negev fold belt in the Sinai, is the result of Late Mesozoic and Cenozoic inversion of a Late Paleozoic and Mesozoic, NE-trending, linear intracontinental basin located within the northern Arabian platform. The southwestern Palmyrides, near the Dead Sea transform fault system and the Anti-Lebanon mountains, are characterized by short wavelength (5-10 km) en echelon folds separated by small intermontane basins that developed mainly in Neogene to Recent times. A new three-dimensional data cube, 60 X 70 km, generated on a Landmark Graphics (TM) workstation and based on approximately 700 km of two-dimensional seismic reflection profiles, elucidates the structure of the upper 10 km of the crust in the southwestern Palmyrides. Visualization of the subsurface structure, which is represented by a prominent Upper Cretaceous reflection surface in the data cube, is augmented by the topography and Bouguer gravity of the same region. Preexisting discontinuities, probable normal fault relicts of the Mesozoic Palmyride rift, likely controlled the development of individual Neogene thrusts. The new subsurface image shows important structural features not identified in outcrop. Short, WNW-trending transcurrent, or transfer, faults link the short, en echelon NE-trending thrust faults and blind thrusts of the Palmyrides. A pervasive regional decollement is not observed, even though Triassic evaporites host local detachments. There has been no wholesale transport of shallower strata on a regional decollement that decouples Mesozoic and Cenozoic rocks from underlying Paleozoic rocks.
Unlike topographic relief, which only roughly resembles subsurface structures, the Bouguer gravity signature of the southwestern Palmyrides closely mimics underlying shallow geologic structures both on a large (~50 km wavelength) and a small (~5-10 km) scale. Relatively uncommon reflections from deformed Paleozoic rocks and the excellent correlation between Bouguer gravity and shallow structures indicate a general concordance between shallow Mesozoic and Cenozoic rocks and deeper Paleozoic rocks. Hence, Paleozoic rocks either deformed together with shallower strata, or structures within Paleozoic rocks controlled the development of shallower Neogene and younger structures.
Our structural analysis and many other recent studies of the region are indicative of minor right-lateral shear coupled with compression in the Palmyrides.

title: Structure and evolution of the petroliferous Euphrates graben system, southeast Syria
abstract: Copyright 1998, AAPG. Reprinted by permission of the AAPG whose permission is required for further use. See also: http://aapgbull.geoscienceworld.org/cgi/content/abstract/82/6/1173; http://atlas.geo.cornell.edu/syria/litak_aapg_bull_1998.htmlThe northwest-trending Euphrates graben system is an aborted intracontinental rift of Late Cretaceous age that has subsequently been hidden by Cenozoic burial. Approximately 100 km wide, the system comprises an extensive network of grabens and half grabens extending some 160 km from the Anah Graben in western Iraq to the Palmyride fold belt in central Syria, where it becomes more subdued. The youngest prerift rocks are presently at a maximum depth of about 5 km. Based primarily on interpretation of 1500 km of seismic reflection profiles and data from 35 wells, we mapped a complex network of numerous branching normal and strike-slip faults, generally striking northwest and west-northwest. Both branched and single-strand linear normal faults of generally steep dip, as well as positive and negative flower structures, are manifest on seismic sections. No single rift-bounding fault is observed; instead, a major flexure coupled with minor normal faulting marks the southwestern edge of the basin, with considerable variation along strike. To the northeast, deformation diminishes on the Rawda high near the Iraqi border. The Euphrates graben system likely formed in a transtensional regime, with active rifting primarily restricted to the Senonian and with an estimated maximum extension of about 6 km. Minor Cenozoic inversion of some structures also is evident. Approximately 30 oil fields have been discovered in the Euphrates graben system since 1984. Recoverable reserves discovered to date reportedly exceed 1 billion barrels of oil and lesser amounts of gas. Light oil is primarily found in Lower Cretaceous sandstone reservoirs juxtaposed by normal faulting against Upper Cretaceous synrift sources and seals.

title: Chemotaxis in Microfluid Channels
abstract: Doctoral thesis in Physics for Danica Wyatt with advisors James Sethna, Carl Franck and committee chair Eberhard BodenschatzUsing microfluidic channels for in vivo experiments in biology reduces the dimensions of an experiment to a cellular scale. This increases precision in the spatiotemporal control of chemical signals applied to a cell membrane which is crucial in quantifying resulting changes in the conformation and distribution of membrane and intracellular proteins. We have designed microfluidic experiments to study chemotaxis in the amoeba Dictyostelium discoideum. In a natural environment, these cells use chemical signaling to begin starvation-induced aggregation. Cells generate a complex pattern of cyclic adenosine monophosphate (cAMP) that drives their migration toward a self-organized central point. To better determine which aspects of a gradient trigger a chemotactic response, we used several microfluidic channels in which local cAMP concentration can be precisely manipulated by controlling flow through the device. We also used high-precision photolysis of molecularly caged cAMP to generate dynamic gradients that could be controlled on subsecond timescales. This led to observation of a number of different cellular mechanisms for turning in a changing gradient and established the necessity for statistical measurements of turning behavior under different conditions. This process was initiated with collection of data from four different stages in cell development that quantified how the tendency to maintain polarization increases with development time.National Science Foundation, Nanobiotechnology Center, Max Planck Institute

title: The Role of Architecture and Tissue Properties in the Structural Integrity of Human Vertebral Cancellous Bone
abstract: Age-related disorders of bone metabolism like osteoporosis may compromise structural integrity of bone and result in fragility fractures, particularly at cancellous bone sites. Several factors contribute to cancellous bone strength, including bone density, architecture, and material properties. Clinical assessment of bone density using dual-energy X-ray absorptiometry (DXA), which is somewhat distorted by the fan-shaped X-ray beam, does not fully account for fracture incidence and only partially correlates with bone strength. Spatial variations in trabecular architecture captured by micro-computed tomography (microCT) have been related to structural behavior using microstructure-based models. However, the impact of material variations is not well understood and should be investigated.

DXA fan-beam magnification was quantified by scanning aluminum rods at several distances above the X-ray source. Projected area and bone mineral content decreased by 1.6-1.8% per centimeter distance above the source, indicating that changes in girth over time would artificially reduce DXA measurements and obscure actual gains associated with growth or interventions.

The ability of DXA to predict bone architecture and material properties was assessed in thoracolumbar specimens from 21 cadavers. T11-L4 was scanned using DXA, and cancellous bone cores drilled from the center of T12 and L2 were scanned at 17 microns using microCT and then compressed uniaxially to failure. DXA and microCT bone mass correlated similarly with cancellous bone stiffness and strength in females but not males. DXA could not account for variations in architecture detected by microCT, particularly in the thoracic spine, for either males or females. MicroCT scans may better assess bone strength in the thoracic spine and could replace DXA scans altogether if measurements could be made non-invasively, accurately, and affordably.

Spatial variations in architecture and material properties were examined with architecture- and material-based finite element (FE) models developed from microCT scans. Homogeneous and heterogeneous material models were examined. FE models were improved by heterogeneity, whether between subjects using specimen-specific uniform properties or within subjects using spatially varying properties. Apparent

stiffness was the same for specimen-specific models, regardless of variations in tissue modulus. The mean tissue modulus, rather than its distribution, appears to drive the overall mechanical behavior for vertebral cancellous bone.

title: Mesozoic-Cenozoic evolution of the Intraplate Euphrates fault system, Syria: Implications for regional tectonics
abstract: This material has been published in Journal of the Geological Society, London, 154, 653-666, 1997, the only definitive repository of the content that has been certified and accepted after peer review. Copyright and all rights therein are retained by The Geological Society of London. See also: http://www.geolsoc.org.uk/template.cfm?name=Journals_JGS_home_page; http://atlas.geo.cornell.edu/syria/litak_gsl_1997.htmlA lack of dramatic surface geologic structures along the Euphrates River in Syria belie a complex tectonic history revealed by newly-released seismic reflection and well data. We document the intraplate Euphrates fault system, characterize the variation in structural style along its 350 km length in Syria, and infer its Mesozoic-Cenozoic tectonic and deformational history. We then relate the deformation of the Euphrates system and other proximate intraplate structures to nearby Arabian plate boundary processes in order to develop a new model for the kinematic evolution of the northern Arabian plate.

Throughout most of Mesozoic time, the Euphrates area experienced minor deposition compared to the Palmyride trough to its southwest, and the Sinjar trough to its northeast. During latest Cretaceous time, however, significant sinistral transtension occurred along the length of the Euphrates fault system in Syria, with graben formation especially noteworthy in southeastern Syria. This episode was probably related to events at nearby plate boundaries, and may have reactivated a zone of weakness formed during Pan-African accretion of the Arabian plate. A Paleogene sag basin formed over the graben system in southeastern Syria. Neogene continental collision along the northern and eastern Arabian plate boundaries precipitated minor reactivation of the Euphrates fault system in a dextral transpressional sense, in concert with significant inversion and the main phase of uplift of the nearby Palmyride and Sinjar mountains.

title: Seismic reflection structure of intracratonic Palmyride fold-thrust belt and surrounding Arabian platform, Syria
abstract: Copyright 1990, AAPG. Reprinted by permission of the AAPG whose permission is required for further use. See also: http://aapgbull.geoscienceworld.org/; http://atlas.geo.cornell.edu/syria/mcbride_aapg_1990.htmlSeismic reflection and drillhole data from central Syria provide a detailed view of the subsurface structure (10-15 km depth) of the relatively little studied intracratonic Palmyride fold and thrust belt. The data set, together with surface geologic mapping, constrain a structural/stratigraphic section spanning the northeast sector of the belt and the surrounding subprovinces of the Arabian platform. The seismic and drillhole data show Mesozoic stratigraphic sequences thickening rapidly into the Palmyrides from the adjacent, arched Paleozoic platforms. Neogene (Alpine) folding and thrusting of the Mesozoic basin, as documented on the seismic data, are sharply restricted to the narrow width of the belt (~100 km), which is in contrast to the relatively undeformed, Phanerozoic strata of the platforms to the north and south.

The regional subsurface structure of the northeastern Palmyrides consists of a northeast-plunging anticlinorium whose outer flanks are marked by smaller superimposed asymmetric, anticlines associated with

outward verging thrusts, giving this part of the belt a rough symmetry. The general structural style of folding is characterized by simple, relatively narrow anticlines and broad synclines that can be traced concordantly from the surface to at least 5 km depth on the seismic data--the level of any decollement appears to be below the imaged Mesozoic sequence. A fundamental feature of the surrounding Arabian platform subprovinces is a deep (~6-7 km, maximum) and pervasive bright reflection that forms the base of the reflective section of the platform but disappears abruptly beneath the Palmyrides. This basal reflector is important as a regional strain marker and may represent a Cambrian/Infracambrian carbonate-evaporite sequence or a remarkably uniform crystalline basement surface.

The seismic and drillhole data support the hypothesis of the Palmyrides beginning as a Permian-Triassic failed rift, connected to the Levantine passive continental margin, that was inverted and complexly deformed by the interfering effects of Cenozoic movements along the Dead Sea (Levant) transform fault system and the Turkish Bitlis (Tauride) convergent zone. The seismic data provide a first-time view into the extent and depth of the early basin formation and subsequent compressional deformation, and as such provide a necessary basis for constraining reconstructions of northern Middle East plate motions.

title: Geologic evolution of the intraplate Palmyride basin and Euphrates fault system, Syria
abstract: Copyright 2001, Museum Nationale D'Histoire Naturelle, France. See also: http://www.mnhn.fr/publication/indexan.html; http://atlas.geo.cornell.edu/syria/sawaf_2001.htmThe Palmyride Basin and the Euphrates fault system are two Late Paleozoic / Mesozoic rifts that formed on the southern margin of the NeoTethys Ocean. Data collected during hydrocarbon exploration are analyzed to determine the geologic history and regional tectonic implications of these structures. The Palmyride Basin formed during Late Paleozoic aulacogen-type rifting and subsequent Mesozoic thermal subsidence and fault reactivation. Basin inversion in the Cenozoic resulted in the formation of the Palmyride fold and thrust belt. In contrast, the Euphrates fault system is an aborted intracontinental rift, formed during the Late Cretaceous, that experienced minor transpression in the Cenozoic. Both these structures are hypothesized to have formed along zones of Proterozoic crustal weakness inherited from the accretion of the Arabian plate. Both regions also contain significant hydrocarbon reserves; predominantly gas in the Palmyride Basin and oil in the Euphrates fault system. The tectonic histories of these features are inseparably linked to the intraplate stresses generated in the northern Arabian plate by the polyphase opening and closing of the adjacent NeoTethys Ocean.

title: Stratigraphy and structure of eastern Syria across the Euphrates depression
abstract: Copyright 1993, Elsevier Science B.V. See also: http://dx.doi.org/10.1016/0040-1951(93)90235-C; http://atlas.geo.cornell.edu/syria/sawaf_tectonophys_1993.htmlAlong a 450 km transect across central Syria seismic reflection data, borehole information, potential field data and surface geologic mapping have been combined to examine the crustal structure of the northern Arabian platform beneath Syria. The transect is surrounded by the major plate boundaries of the Middle East, including the Dead Sea transform fault system along the Levantine margin to the west, the Bitlis suture and East Anatolian fault to the north, and the Zagros collisional belt to the northeast and east. Three main tectonic provinces of the northern Arabian platform in Syria are crossed by this transect from south to north: the Rutbah uplift, the Palmyra fold-thrust belt, and the Aleppo plateau. The Rutbah uplift in southern Syria is a broad, domal basement-cored structure with a thick

Phanerozoic (mostly Paleozoic) cover of 6-7 km. Isopachs based on well and seismic reflection data indicate that this region was an early Paleozoic depocenter. The Palmyra fold-thrust belt, the northeastern arm of the Syrian Arc, is a northeast- southwest trending intracontinental mountain belt that acts as a mobile tectonic zone between the relatively stable Rutbah uplift to the south and the less stable Aleppo plateau to the north. Short wavelength en echelon folds characterized by relatively steep, faulted southeast flanks dominate in the southwest, most strongly deformed segment of the belt, while a complex system of deeply rooted faults and broad folds characterize the northeast region, described in this study. The Aleppo plateau lies immediately north of the Palmyride belt, with a combined Paleozoic and Mesozoic sedimentary section that averages 4-5 km in thickness. Although this region appears relatively undeformed on seismic reflection data when compared to Palmyride deformation, a system of near vertical, probable strike-slip faults crosscut the region in a dominantly northeasterly direction.

Gravity and magnetic modeling constrains the deep crustal structure along the transect. The crustal thickness is estimated to be approximately 38 km. Interpretation of the gravity data indicates two different crustal blocks beneath the Rutbah uplift and the Aleppo plateau, and the presence of a crustal-penetrating, high-density body beneath the northeast Palmyrides. The two distinct crustal blocks suggest that they were accreted possibly along a suture zone and/or a major strike-slip fault zone located approximately in the present-day position of the Palmyrides. The age of the accretion is estimated to be Proterozoic or early Cambrian, based on the observation of a pervasive reflection (interpreted as the Middle Cambrian Burj limestone) in the Rutbah uplift and in the Aleppo plateau and by analogy with the well-mapped Proterozoic sutures of the Arabian shield to the south.

title: Upper crustal velocity structure and basement morphology beneath the intracontinental Palmyride fold-thrust belt and north Arabian platform in Syria
abstract: An edited version of this paper was published in Geophysical Journal International by Blackwell Publishing. Copyright 1993, Blackwell Publishing. See also: http://www.blackwellpublishing.com/journal.asp?ref=0956-540X&site=1; http://atlas.geo.cornell.edu/syria/seber_gji_1993.htmThe intracontinental Palmyride fold-thrust belt, which is the site of an inverted Mesozoic rift, is sandwiched between two crustal blocks, the Aleppo plateau in the north and the Rutbah uplift in the south. The 400 x 100 km belt merges with the Dead Sea fault system in the southwest and gradually ends near the Euphrates depression in the northeast. Very dense (i.e., 100 m geophone spacing), reversed and multifold seismic refraction profiling was

carried out to map approximately the upper 15 km of the crust in the early 1970s. These refraction data are utilized to model sedimentary rock thickness, seismic velocity, and basement morphology. Extensive data coverage also enables identification of the major faults of the region. A 2-D ray tracing technique is used in the modeling. Interpretation of these data indicates that five distinct velocity layers characterize the upper crust of the northern Arabian platform in Syria. The P-wave velocities within these layers are (in km s-1): 2.0-2.8, 4.0-4.4, 5.2-5.3 , 5.5-5.7, corresponding to sedimentary rocks from Quaternary to late Precambrian in age, and 5.9-6.0, corresponding to metamorphic basement. A comparison of the velocity models with the available drill hole information and seismic reflection profiles shows strong velocity variations in a given geologic formation, depending on the depth and location of the formation. The depth to metamorphic basement beneath the Palmyride fold belt clearly shows a deep trough, filled with Phanerozoic sedimentary rocks. These rocks decrease in thickness from about 11 km in the southwest to about 9 km in the central segment of the belt. The basement depth is about 6 km in the Aleppo plateau and not less than 8 km in the Rutbah uplift. Deeper basement in the Rutbah uplift is probably the result of a Precambrian rifting episode, clearly identified to the south in Jordan and Saudi Arabia. Cenozoic crustal shortening of about 20-25% across the southwestern segment of the Palmyride belt has not been sufficient to substantially reduce the size of the basement trough beneath this mountain belt. Finally, northeast decreasing basement depth in the Palmyrides supports the idea that the Palmyride Mesozoic rifting was developed as an aulacogen of the rifted Levantine margin along the eastern Mediterranean.

title: CUMULATIVE RISK AND BEHAVIORAL PROBLEMS IN EARLY ADOLESCENCE: TESTING THE MEDIATION AND MODERATION ROLES OF DYSREGULATION IN MULTIPL BIOLOGICAL STRESS SYSTEMS
abstract: Gary W. Evans, John J. EckenrodeIn an attempt to understand how cumulative risk influences behavioral problems in early adolescence, this study focuses on the mediating and the moderating roles of dysregulation in multiple biological stress systems. In a sample of 223 seventh- and eighth-grade children, cumulative risk included psychosocial factors (family turmoil, parent-child separation, exposure to violence) and physical factors (noise, crowding, housing quality) and sociodemographic characteristics of the adolescents? families (maternal high school drop out, single parent, and poverty). Physiological markers of biological stress dysregulation were cortisol, epinephrine, norepinephrine, fat deposition, resting systolic and diastolic blood pressure, and systolic and diastolic reactivity and recovery. There were adverse effects of cumulative risk on both internalizing and externalizing behaviors. Cumulative risk and biological stress dysregulation had a curvilinear relationship. We found that biological stress dysregulation may have an indirect effect on the relation between cumulative risk and internalizing behaviors. Further, older children were more likely to develop internalizing behaviors when they were exposed to cumulative risk. Biological stress dysregulation moderated the effects of cumulative risk on externalizing behaviors; the inefficient stress regulation in multiple biological systems made children more vulnerable to externalizing behavioral problems when they were living in cumulative risk environment. The importance of understanding both

mediating and moderating roles of biological stress dysregulation for behavioral problems was discussed.

title: Healthy, Wealthy, and Wise? The Link Between Ideology and Health in America
abstract: The purpose of this study is to explore the relationship between ideological beliefs and individual self-reported health in America between the years 1993 and 2004. A distinction between particular ideologies and ruling ideology is made. Particular ideologies are created by social interaction as a product of history and are used as tools for categorizing and structuring observations, experiences, ideas, and action. Individuals need the structures provided by particular ideologies both to understand and to act upon their world. A ruling ideology develops when those in power knit together multiple particular ideologies to create a unified system of thought that presents an easily accepted and internalized set of normative behaviors, thought-patterns, and ideals, in order to protect their social position.

Preliminary data analysis revealed that the majority of Americans believe they have good health. These results aided in the development of several research questions. If ideology is as pervasive as suggested by the literature, then is there anything about the current ideologies that precipitate widespread belief by individuals that they have good health? Could ideology give a cohesive worldview to individuals, thus reducing their stress of being outside the norm? Or, could ideology provide individuals with normative prescriptions for behaviors that are good for their health, such as reducing smoking and binge-drinking? Do the benefits of a cohesive worldview or of behavioral health norms outweigh the consequences of the possible false consciousness that may result simultaneously?

Four propositions suggesting connections between ideology and self-reported health are evaluated using binary logistic regression analyses and data from 1993 through 2004 contained in the General Social Survey. I predicted that respondents who had internalized the dominant particular ideologies or ruling ideology of the era would have better health than those who adhered to a different paradigm. Health is measured as poor or good perceptions of self-health.

The findings of the analyses show moderate support for three out of four of my propositions. Economic and social ideological beliefs have a significant relationship with self-reported health net of demographic controls and material indicators. Using a composite scale to give more breadth to the measurement, religious ideology is also seen as a predictor of self-reported health. The fourth proposition concerning ruling ideology found little support using this dataset. Despite the support garnered for psychosocial theory through the significance of the variables indicating particular ideology, support for neo-materialist theory was also revealed. In fact, the material indicators showed the strongest and most robust relationships with health status. In many cases, they overwhelmed the other variables. However, in contradiction to epidemiological research, health behaviors do not contribute to explaining to self-reported health. The limitations of the study and the implications of the results in light of the research questions are discussed at length in the conclusion.

title: Morality and Movies: What are People Thinking? A Content Analysis of Informal Movie Reviews Online
abstract: It has long been assumed that movies can have an influence on moral development and moral thought. The content analysis presented here examines whether and how people who post informal reviews online think about moral issues related to the films, and how that fits with theories about moral development and the role of moral thoughts in entertainment. The results indicate that, in this context, conscious thoughts about moral issues are scarce, although they increase significantly when a movie is morally ambiguous. Most of the comments about moral issues reflect on the possible moral effects on others rather than on the self. This result casts some doubt on the assumption that films can be a tool for moral self-development. Other results show that moral comments about elements beyond the plot and characters (creators of the film, general audience and the world at large) are almost as frequent as those about the storyline, and that people

use the level of moral complexity of a film to evaluate its overall quality. It would appear that the role of moral thoughts is more varied than previous theoretical models indicate. Future research in the area should perhaps incorporate considerations about moral ambiguity of a movie, moral thoughts beyond plot issues, and different roles that moral thoughts play in audience?s interpretations of movies.

title: By Statement and Omission: Media Representations of School Failure in the Standards Era
abstract: In this thesis, I explore media content as a gauge of the dominant American cultural norms, values, and interests around school failure. I problematize the persistence of inequalities in American schools, and situate this problem in the historical context of the standards movement in American education in general and the No Child Left Behind Act, signed into law in 2002, in particular. To help construct this narrative of school failure, I anchor this history in the social structures of racial inequality, in the role of ideology in shaping policy and perception, and in the concept of exploring media representations to gain insight into the cultural understanding of each of these.
I center my investigation in a frame analysis of the content of newspaper articles from New York State, 2000-2006, which tell the story of school failure. The depictions of failure in schools, as represented in the news articles, are persistent ways to communicate mainstream social norms and values and to show who resides outside of that mainstream. This study showed, through analysis of the explanatory frames that emerged from the sample of articles, that the dominant American ideology of meritocracy, colorblindness, and equality of opportunity creates an understanding of failure is as an individual shortcoming, showing who isn?t trying hard enough, who resides out of the mainstream, and who isn?t normal?in this case, white, suburban, and middle-class. I argue that this understanding conceals real structural inequalities that make success all but impossible for many students and can impede efforts to at effective reform.

title: THEATRE OF THE OPPRESSED IN US PRISONS: EIGHT YEARS OF WORKING WITH ADULT AND YOUTH PRISONERS EXAMINED
abstract: Ph.D Dissertation in Theatre StudiesIn this dissertation, I locate my theatre work with prisoners within topics of interest in Performance Studies: examining performativity, troubling the representation of imprisoned bodies, considering the roles of ritual, play and liminality within the location of prison. I examine

the limitations and the ethics of working with prisoners, and I have stayed focused on the prisoners' abilities to mediate and perform practical topics of interest to them using the Theatre of the Oppressed methods (such as staying connected to family and re-entry). My dissertation furthers the growing interest in critiquing Boal's techniques and in theorizing how they work and what they can and cannot achieve. For example, I consider the purpose of fetishizing images into icons and symbols in Image Theatre and critique my own use of the "Joker" role as a participant-observer coming in from outside the prison. I also consider the Brechtian heritage of Boal's work in theory and practice, especially in relationship to Brecht's Lehrstuck, and I seek to reconcile modern and postmodern theoretical and practical approaches to understanding performance and critical deliberation using TO work in prisons. This work has ramifications for thinking about visual perception and Image Theatre. It also brings sociolinguistic "positioning theory" into contact with the concept of "restored behavior" through examining the practices of TO's forum theatre. A discourse surrounding the word "respect" and the conception of "prison values" as a social critique defined by prisoners in this research are keynotes to this work.

title: Global Positioning System measurements of strain accumulation and slip transfer through the restraining bend along the Dead Sea fault system in Lebanon
abstract: An edited version of this paper was published in Geophysical Journal International by Blackwell Publishing. Blackwell Publishing retains the copyright to this paper (Copyright 2007). See also: http://www.blackwell-synergy.com/doi/abs/10.1111/j.1365-246X.2006.03328.x; http://atlas.geo.cornell.edu/deadsea/publications/Gomez2007_GJI.htmApproximately 4 yr of campaign and continuous Global Positioning System (GPS) measurements across the Dead Sea fault system (DSFS) in Lebanon provide direct measurements of interseismic strain accumulation along a 200-km-long restraining bend in this continental transform fault. Late Cenozoic transpression within this restraining bend has maintained more than 3000 m of topography in the Mount Lebanon and Anti-Lebanon ranges. The GPS velocity field indicates 4-5 mm yr-1 of relative plate motion is transferred through the restraining bend to the northern continuation of the DSFS in northwestern Syria. Near-field GPS velocities are generally parallel to the major, left-lateral strike-slip faults, suggesting that much of the expected convergence across the restraining bend is likely accommodated by different structures beyond the aperture of the GPS network (e.g. offshore Lebanon and, possibly, the Palmyride fold belt in SW Syria). Hence, these geodetic results suggest a partitioning of crustal deformation involving strike-slip displacements in the interior of the restraining bend, and crustal shortening in the outer part of the restraining bend. Within the uncertainties, the GPS-based rates of fault slip compare well with Holocene-averaged estimates of slip along the two principal strike-slip faults: the Yammouneh and Serghaya faults. Of these two faults, more slip occurs on the Yammouneh fault, which constitutes the primary plate boundary structure between the Arabia and Sinai plates. Hence, the Yammouneh fault is the structural linkage that transfers slip to the northern part of the transform in northwestern Syria. From the perspective of the regional earthquake hazard, the Yammouneh fault is presently locked and accumulating interseismic strain.

title: Stereo Viewing Interface for Workstations
abstract: Three dimensional data sets are becoming widespread in scientific simulations and analysis of physical systems. Applications ranging from fluid simulations to medical imaging require understanding of three dimensional (3D) data. Researchers often produce images from the data to aid in understanding. In the resulting images, monocular depth cues such as object size, parallax motion, and shading help to interpret 3D data. However, viewing 3D data is enhanced by using stereo pairs so that binocular depth cues are available. There are several schemes for producing stereo pairs on the screen of a workstation (e.g. liquid crystal shutters, vibrating mirrors or cylinderical lens). We describe here a liquid crystal shutter system which is easy and inexpensive to construct vibrating mirrors or cylinderical lens). We describe here a liquid crystal shutter system which is easy and inexpensive to construct. Using liquid-crystal shutter glasses designed for video games, it is possible to construct an inexpensive stereo viewing interface to any personal computer or workstation which has hardware double-buffering of the display screen and which can produce an RS-232 character. The resulting display exhibits strong stereo depth cues. Flicker is noticeable and depends on the refresh rate of the monitor as well as the speed with which the double-buffered display can be changed. On the IBM RISC System 6000, equipped with the GL display card (part number xxx), the flicker is moderate, the brightness good, and the stereo effect very stable. The description given here will assume an IBM RISC System 6000. There are two parts to the system: the software to display two images in the double buffer and the hardware which converts an RS-232 character to the waveform necessary to drive the liquid-crystal glasses. Clearly the software will have to be modified for other systems, although it should run virtually unmodified on Silicon Graphics machines, such as the Personal IRIS.

title: Parallel Finite Element Analysis of Biomechanical Structures on the Ncube 6400
abstract: This paper presents parallel 3-D finite element analysis for distributed memory multiprocessors. Traditionally, finite element analysis has been performed on sequential computers. Current research in high performance finite element analysis shows considerable promise for fast, efficient implementation on MIMD and SIMD computers.
This paper demonstrates the use of a standard, banded Cholesky method for solving the finite element system of equations. The uniformity of the underlying data distribution ensures high performance due to load balance. Moreover, since a distributed banded Cholesky algorithm is likely to a part of a standard parallel numerical library, it reduces the burden on the applications programmer, making this method simpler to implement than the substructuring method. Since a parallel solver requires the rows of the coefficient matrix to be distributed in a wrap fashion, it might appear that the assembly of the element stiffness matrices would not be efficient. However, as shown in this paper, the calculation of element stiffness matrices, assembly and the calculation of Gauss-point stresses can be done efficiently in parallel without any inter-processor communication. In fact, once nodal coordinates and element connectivity is made available to all processors,

message passing is required only during the factorization and solution stages.
The next few sections describe how parallelism was exploited during the assembly, solution and stress recovery strages of the finite element analysis. The parallel program developed was tested on large 3-D finite element problems arising from biomechanical structural systems, on an Ncube 6400. High performance Basic Linear Algebra Subprograms (BLAS) were used to improve the execution speed.

title: Discrete Hedging Under Piecewise Linear Risk Management
abstract: In an incomplete market it is usually impossible to eliminate the intrinsic risk of an option. In this case quadratic risk-minimization is often used to determine a hedging strategy. However, it may be more natural to use piecewise linear risk-minimization since in this case the risk is measured in actual dollars (not dollars squared). We investigate hedging strategies using piecewise linear risk-minimization. We illustrate that piecewise linear risk-minimization often leads to smaller expected total hedging cost and significantly different, possibly more desirable, hedging strategies from those of quadratic risk minimization. The distributions of the total hedging cost and risk show that hedging strategies obtained by piecewise linear risk-minimization have a larger probability of small cost and risk, though they also have a very small probability of larger cost and risk. Comparative numerical results are provided.

title: Access Normalization: Loop Restructuring for NUMA Compilers
abstract: A common feature of many scalable parallel machines is non-uniform memory access - a processor can access data in its local memory ten to a thousand times faster than it can access local data. In addition, when a number of remote accesses must be made, it is usually more efficient to use block transfers of data rather than to use many small messages. To run well on such machines, software must exploit these features. We believe it is too onerous for a programmer to do this by hand, so we have been exploring the use of restructuring compiler technology for this purpose. In this paper, we start with a language like FORTRAN-D with user-specified data distributions and develop a systematic loop transformation strategy called access normalization that restructures loop nests to exploit both locality and block transfers whenever possible. We demonstrate the power of our techniques using routines from the BLAS (Basic Linear Algebra Subprograms) library. Our loop transformation strategy is expressed in the framework of invertible matrcies and integer lattice theory, and it is an important generalization of Banerjee's framework of unimodular matrices.

title: The Valuation of Convertible Bonds With Credit Risk
abstract: Convertible bonds are typically issued by firms which have both relatively high growth and quite high risk. Convertibles can be difficult to value, given their hybrid nature of containing elements of both debt and equity. Further complications arise due to the frequent presence of additional options such as callability and puttability, and contractual complexities such as trigger prices and "soft call" provisions, in which the ability of the issuing firm to exercise its option to call is dependent upon the history of its stock price. This paper explores the valuation of convertible bonds subject to credit risk using an approach based on the numerical solution of a system of coupled linear complementarity problems. We argue that many of the existing modes, such as that of Tsiveriotis and Fernandes (1998), are unsatisfactory in that they do not explicitly specify what happens in the event of a default by the issuing firm. In fact, many of the differences between existing models appear to arise from varying implicit assumptions about this. In existing models it is assumed that upon a default either nothing happens to the firm's stock price or else it instantly jumps to zero. Neither of these alternatives seems to be entirely appealing: while it is a significant event, implying that there will be some market reaction to the news of a default, a sudden and complete collapse is rare. Consequently, we propose a model where the firm's stock price falls by some specified percentage between 0% and 100% (which includes the limiting cases implicit in existing models). We also present a detailed description of our numerical algorithm, which uses a partially implicit method to decouple the system of linear complementarity problems at each timestep. Numerical examples illustrating the convergence properties of the algorithm are provided.

title: Dynamic Hedging in a Volatile Market
abstract: In financial markets, errors in option hedging can arise from two sources. First, the option value is a nonlinear function of the underlying; therefore, hedging is instantaneous and hedging with discrete rebalancing gives rise to error. Frequent rebalancing can be impractical due to transaction costs. Second, errors in specifying the model for the underlying price movement (model specification error) can lead to poor hedge performance. In this article, we compare the effectiveness of dynamic hedging using the constant volatility method, the implied volatility method, and the recent volatility function method [3]. We provide evidence that dynamic hedging using the volatility function method [3] produces smaller hedge error. We assume that there are no transaction costs, and both the risk-free interest rate r and the dividend rate q are constant.

title: Efficient Calculation of Jacobian and Adjoint Vector Products in Wave Propagational Inverse Problems Using Automatic Differentiation
abstract: Wave propagational inverse problems arise in several applications including medical imaging and geophysical exploration. In these problems, one is interested in obtaining the parameters describing the medium from its response to excitations. The problems are characterized by their large size, and by the hyperbolic equation which models the physical phenomena. The inverse problems are often posed as a nonlinear data-fitting where the unknown parameters are found by minimizing the misfit between the predicted data and the actual data. In order to solve the problem numerically using a gradient-type approach, one must calculate the action of the Jacobian and its adjoint on a given vector. In this paper, we explore the use of automatic differentiation (AD) to develop codes that perform these calculations. We show that by exploiting structure at 2 scales, we can arrive at a very efficient code whose main components are produced by AD. In the first scale we exploit the time-stepping nature of the hyperbolic solver by using the "Extended Jacobian" framework. In the second (finer) scale, we exploit the finite difference stencil in order to make explicit use of the sparsity in the dependence of the output variables to the input variables. The main ideas in this work are illustrated with a simpler, one-dimensional version of the problem. Numerical results are given for both one- and two- dimensional problems. We present computational templates that can be used in conjunction with optimization packages to solve the inverse problem.

title: Dynamic Hedging with a Deterministic Local Volatility Function Model
abstract: We compare the dynamic hedging performance of the deterministic local volatility function approach with the implied/constant volatility method. Using an example in which the underlying price follows an absolute diffusion process, we illustrate that hedge parameters computed from the implied/constant volatility method can have significant error even though the implied volatility method is able to calibrate the current option prices of different strikes and maturities. In particular the delta hedge parameter produced by the implied/constant volatility method is consistently significantly larger than that of the exact delta when the underlying price follows an absolute diffusion.

title: An Object-Oriented Framework For Valuing Shout Options on High-Performance Computer Architectures
abstract: A shout option is a financial contract which allows the holder to change the payoff during the lifetime of the contract. For example, the holder could have the right to set the strike price to the current value of the underlying asset. Complex versions of these options are embedded in financial products which offer various types of maturity guarantees such as segregated funds marketed by Canadian insurance companies. The value of these options can be determined by solving a collection of coupled partial differential equations (PDEs). In this work we develop an extensible, object-oriented framework for valuing these contracts which

is capable of exploiting modern, high-performance supercomputing architectures. We use this framework to study and illustrate practical aspects of valuing and hedging these contracts.

title: Three-Dimensional Acoustic Visualization of Zooplankton Patchiness
abstract: Acoustic data were collected and visualized to characterize the 3-dimensional patchiness of zooplankton at a thermally stratified site on Georges Bank. The work was carried out as part of a field study conducted to examine the effects of springtime water-column stratification on the distributions of zooplankton and larval fish on the Bank. The acoustic data were acquired as the ship steamed a survey grid relative to the track of a surface drifter with a subsurface drogue. Although quite irregular in geographical coordinate space, the ship's track relative to the moving water closely matched the intended grid pattern once the drifter's movement in the tidal flow was taken into account. After changing coordinate systems to compensate for tidal advection, the acoustic data set was transformed from its curtain-like distribution in 3-dimensional space to a volumetric distribution. Two-dimensional point kriging was performed on the irregularly spaced data from each 2-m-thick depth stratum to produce a series of 2-dimensional, regularly spaced data grids. These data grids were then stacked to construct the 3-dimensional data grid required for volumetric visualization. A similar procedure was followed with the error variance values produced at each grid point through kriging to construct a three-dimensional, volumetric distribution of the error variance. To examine zooplankton patchiness within the surveyed volume of water, isosurfaces corresponding to specific levels of acoustic backscatter were highlighted in the visualization. The 3-dimensional distribution of error variance was used to control the opacity of the isosurfaces to provide an objective, visual approach for displaying the statistical confidence one can have in the patches detected. In this survey, the ship steamed directly over a large, southwest- to northeast-oriented patch of zooplankton on at least three different passes. It also steamed over several smaller patches. The vertically compressed nature of the patches and their high degree of spatial heterogeneity in the horizontal plane are characteristic of the zooplankton distributions found in the deeper, seasonally stratified portions of Georges Bank.

title: Option Pricing and Linear Complementarity
abstract: Many American option pricing models can be formulated as linear complementarity problems (LCPs) involving partial differential operators. While recent work with this approach has mainly addressed the model classes where the resulting LCPs are highly structured and can be solved fairly easily, this paper discusses a variety of option pricing models that are formulated as partial differential complementarity problems (PDCPs) of the convection-diffusion kind whose numerical solution depends on a better understanding of LCP methods. Specifically, we present second-order upwind finite difference schemes for the PDCPs and derive fundamental properties of the resulting discretized LCPs that are essential for the convergence and stability of the finite difference schemes and for the numerical solution of the LCPs by effective computational methods. Numerical results are reported to support the benefits of the proposed schemes. A main objective of this presentation is to elucidate the important role that the LCP has to play in the fast and effective numerical pricing of American options.

title: Hedging a Portfolio of Derivatives by Modeling Cost
abstract: We consider the problem of hedging the loss of a given portfolio of derivatives using a set of more liquid derivative instruments. We illustrate why the typical mathematical formulation for this hedging problem is ill-posed. We propose to determine a hedging portfolio by minimizing a proportional cost subject to an upper bound on the hedge risk; this bound is typically slightly larger than the optimal hedge risk achievable without cost consideration. We illustrate that the optimal hedging portfolio obtained by the proposed method is attractive since it consists of fewer instruments with a comparable risk. Finally we illustrate the importance of modeling volatility uncertainty in hedge risk minimization.

title: Reconstructing the Unknown Local Volatility Function
abstract: Using market European option prices, a method for computing a smooth local volatility function in a 1-factor continuous diffusion model is proposed. Smoothness is introduced to facilitate accurate approximation of the local volatility function from a finite set of observation data. Assuming that the underlying indeed follows a 1-factor model, it is emphasized that accurately approximating the local volatility function prescribing the 1-factor model is crucial in hedging even simple European options, and pricing exotic options. A spline functional approach is used: the local volatility function is represented by a spline whose values at chosen knots are determined by solving a constrained nonlinear optimization problem. The optimization formulation is amenable to various option evaluation methods; a partial differential equation implementation is discussed. Using a synthetic European call option example, we illustrate the capability of the proposed method in reconstructing the unknown local volatility function. Accuracy of pricing and hedging is also illustrated. Moreover, it is demonstrated that, using different implied volatilities for options with different strikes/maturities can produce erroneous hedge factors if the underlying follows a 1-factor model. In addition, real market European call option data on the S and P 500 stock index is used to compute the local volatility function; stability of the approach is demonstrated.

title: A Newton Method for American Option Pricing
abstract: The variational inequality formulation provides a mechanism to determine both the option value and the early exercise curve implicitly [17]. Standard finite difference approximation typically leads to linear complementarity problems with tridiagonal coefficient matrices. The second order upwind finite difference formulation gives rise to finite dimensional linear complementarity problems with nontridiagonal matrices, whereas the upstream weighting finite difference approach with the van Leer flux limiter for the convection term [19, 22] yields nonlinear complementarity problems. We propose a Newton type interior-point method for solving discretized complementarity/variational inequality problems that arise in the American option valuation. We illustrate that the proposed method on average solves a discretized problem in 2 ~ 5 iterations to an appropriate accuracy. More importantly, the average number of iterations required does not seem to depend on the number of discretization points in the spatial dimension; the average number of iterations actually decreases as the time discretization becomes finer. The arbitrage condition for the fair value of the

American option requires that the delta hedge factor be continuous. We investigate continuity of the delta factor approximation using the complementarity approach, the binomial method, and the explicit payoff method. We illustrate that, while the (implicit finite difference) complementarity approach yields continuous delta hedge factors, both the binomial method and the explicit payoff method (with the implicit finite difference) yield discontinuous delta approximations. Hence the early exercise curve computed from the binomial method and the explicit payoff method can be inaccurate. In addition, it is demonstrated that the delta factor computed using the Crank-Nicolson method with complementarity approach oscillates around the early exercise curve.

title: Efficient Calculation of Jacobian and Adjoint Vector Products in Wave Propagational Inverse Problems Using Automatic Differentiation
abstract: Wave propagational inverse problems arise in several applications including medical imaging and geophysical exploration. In these problems, one is interested in obtaining the parameters describing the medium from its response to excitations. The problems are characterized by their large size, and by the hyperbolic equation which models the physical phenomena. The inverse problems are often posed as a nonlinear data-fitting where the unknown parameters are found by minimizing the misfit between the predicted data and the actual data. In order to solve the problem numerically using a gradient-type approach, one must calculate the action of the Jacobian and its adjoint on a given vector. In this paper, we explore the use of automatic differentiation (AD) to develop codes that perform these calculations. We show that by exploiting structure at 2 scales, we can arrive at a very efficient code whose main components are produced by AD. In the first scale we exploit the time-stepping nature of the hyperbolic solver by using the \Extended Jacobian" framework. In the second (finer) scale, we exploit the finite difference stencil in order to make explicit use of the sparsity in the dependence of the output variables to the input variables. The main ideas in this work are illustrated with a simpler, one-dimensional version of the problem. Numerical results are given for both one- and two- dimensional problems. We present computational templates that can be used in conjunction with optimization packages to solve the inverse problem.

title: Segmentation of Pulmonary Nodule Images Using Total Variation Minimization
abstract: Total variation minimization has edge preserving and enhancing properties which make it suitable for image segmentation. We present Image Simplification, a new formulation and algorithm for image segmentation. We illustrate the edge enhancing properties of total variation minimization in a discrete setting by giving exact solutions to the problem for piecewise constant functions in the presence of noise. In this case, edges can be exactly recovered if the noise is sufficiently small. After optimization, segmentation is completed using edge detection. We find that our image segmentation approach yields good results when applied to the segmentation of pulmonary nodules.

title: Dynamic Hedging With a Deterministic Local Volatility Function Model
abstract: We compare the dynamic hedging performance of the deterministic local volatility function approach with the implied/constant volatility method. Using an example in which the underlying price follows an absolute diffusion process, we illustrate that hedge parameters computed from the implied/constant volatility method can have significant error even though the implied volatility method is able to calibrate the current option prices of different strikes and maturities. In particular the delta hedge parameter produced by the implied/constant volatility method is consistently significantly larger than that of the exact delta when the underlying price follows an absolute diffusion. In order to compute a better hedge parameter, accurate estimation of the local volatility function in a region surrounding the current asset price is crucial. We illustrate that a suitably implemented volatility function method can estimate this local volatility function sufficiently accurately to generate more accurate hedge parameters. Hedging using this volatility function for the absolute diffusion example leads to a smaller average absolute hedging error when compared with using the implied/constant volatility rate. When comparing the hedging performance in the S and P 500 index option market as well as the S and P 500 futures option market, we similarly observe that the delta hedge parameter from the implied/constant volatility method is typically greater than that using the volatility function approach. Examination of the hedging error reveals that using a larger delta factor greater than that of the true volatility yields more positive average hedging error, assuming the underlying follows a deterministic volatility model. We observe that, in both the S and P 500 index option market and futures option market, the average absolute hedging error using the volatility function approach is smaller than that of the implied/constant volatility method for a sufficiently long hedging horizon, approximately 17 days for the S and P 500 index options and 6 days for the S and P 500 futures options. In addition, the average hedging error using the volatility function approach is always smaller than that of the implied/constant volatility method.

title: An MPEC Approach to Inverse Pricing of American Options: The Case of an Implied Volatility Surface
abstract: This paper presents a novel approach to deal with the computation of an implied volatility surface of American options written on a risky asset. The approach is based on the simple observation that this computational problem is the inverse of the forward pricing problem of American options. As detailed in [17], the latter forward problem can be modeled by a discretized partial differential linear complementarity system. As such, the inverse problem, i.e., the implied volatility problem, becomes an instance of a Mathematical Program with Equilibrium Constraints, which is a class of constrained optimization problem with a finite-dimensional parametric linear comlementarity system as part of its constraints. Two methods for solving an MPEC are described and applied to the problem of computing and implied volatility surface of American options. Some computational results on experimental data are reported.

title: Efficiency Improvements for Pricing American Options with a Stochastic Mesh
abstract: rlo simulation. First, we develop a mesh-based, biased-low estimator. By recursively averaging the low and high estimators at each stage, we obtain a significantly more accurate point estimator at each of the mesh points. Second, adapt the importance sampling ideas for simulation of European path-dependent options in Glasserman, Heidelberger, and Shahabuddin (1998a) to pricing of American options with a stochastic mesh.

Third, we sketch generalizations of the mesh method and we discuss links with other techniques for valuing American options. Our empirical results show that the bias-reduced point estimates are much more accurate than the standard mesh-method point estimators. Importance sampling is found to increase accuracy for a smooth option-payoff functions, while variance increases are possible for non-smooth payoffs.

title: An efficient trust region method for unconstrained discrete-time optimal control problems
abstract: Discrete-time optimal control (DTOC) problems are large-scale optimization problems with a dynamic structure. In previous work this structure has been exploited to provide very fast and efficient local procedures. Two examples are the differential dynamic programming algorithm (DDP) and the stagewise Newton procedure -- both require only O(N) operations per iteration, where N is the number of timesteps. Both exhibit a quadratic convergence rate. However, most algorithms in this category do not have a satisfactory global convergence strategy. The most popular global strategy is shifting: this sometimes works poorly due to the lack of automatic adjustment to the shifting element. In this paper we propose a method that incorporates the trust region idea with the local stagewise Newton's method. This method possesses advantages of both the trust region idea and the stagewise Newton's method, i.e., our proposed method has strong global and local convergence properties yet remains economical. Preliminary numerical results are presented to illustrate the behavior of the proposed algorithm. We also collect in the Appendix some DTOC problems that have appeared in the literature.

title: Robustly Hedging Variable Annuities with Guarantees Under Jump and Volatility Risks
abstract: Accurately quantifying and robustly hedging options embedded in the guarantees of variable annuities is a crucial task for insurance companies in preventing excessive liabilities. Due to sensitivities of the benefits to tails of the account value distribution, a simple Black-Scholes model is inadequate. A model which realistically describes the real world price dynamics over a long time horizon is essential for the risk management of the variable annuities. In this paper, both jump risk and volatility risk are considered for risk management of lookback options embedded in guarantees with a ratchet feature. We evaluate relative performances of delta hedging and dynamic discrete risk minimization hedging strategies. Using the underlying as the hedging instrument, we show that, under a Black-Scholes model, local risk minimization hedging is significantly better than delta hedging. In addition, we compare risk minimization hedging using the underlying with that of using standard options. We demonstrate that, under a Merton's jump diffusion model, hedging using standard options is superior to hedging using the underlying in terms of the risk reduction. Finally we consider a market model for volatility risks in which the at-the-money implied volatility is a state variable. We compute risk minimization hedging by modeling at-the-money Black-Scholes implied volatility explicitly; the hedging effectiveness is evaluated, however, under a joint underlying and implied volatility model which also includes instantaneous volatility risk. Our computational results suggest that, when implied volatility risk is suitably modeled, risk minimization hedging using standard options, compared to hedging using the underlying, can potentially be more effective in risk reduction under both jump and volatility risks.

title: Hedging guarantees in variable annuities (under both market and interest rate risks)
abstract: In order to prevent possibly very large losses, insurance companies have to devise risk management strategies for the guarantees provided by variable annuities. When hedging the options embedded in these guarantees, due to their long maturities and sensitivity to the underlying accounts tail distributions, it is important to use an appropriate model for the stochastic evolution of the account values as well as the stochastic interest rates. This paper illustrates the discrete hedging of lookback options embedded in guarantees with ratchet features, under jump risk and interest rate risk. Since discrete hedging and the model considered for the underlying price dynamics lead to an incomplete financial market, we compute hedging strategies using local risk minimization. Our numerical results show that computing the hedging strategies under a joint model for the real-world underlying price dynamics and the short interest rates, leads to effective risk reduction. We investigate the performance of hedging using underlying assets and hedging using liquid options. We illustrate that the additional effectiveness in risk reduction, achieved by hedging using options instead of the underlying, can be lost if the interest risk is not accurately modeled in the hedging computation. However, when both equity and interest rate risks are appropriately modeled, hedging with options is superior to hedging with the underlying assets. We also analyze the sensitivity of the hedging performance to the correlation between the underlying asset and the short interest rate.

title: Computing Eigenvalues and Eigenvectors of a Dense Real Symmetric Matrix on the Ncube 6400
abstract: This report demonstrates parallel versions of the Eispack functions TRED2 and TQL2 for finding all eigenvalues and eigenvectors of a dense, real symmetric matrix on the Ncube 6400. There are several

techniques for solving this problem. An efficient and accurate method is tridiagonalization of the original matrix A (TRED2), followed by application of the QR method on the resulting tridiagonal matrix (TQL2). Since the eigenvalues are the roots of a characteristic polynomial, bisection and inverse iteration can be used to compute all eigenvalues and eigenvectors. This method is significantly faster than the QR method provided the eigenvalues are well separated. This technical report will also describe the algorithms TREDs and TQL2 and their parallel counterparts in greater detail. The results of numerical experiments on large problems on a 1024 processors Ncube 6400 are also presented.

title: Stiffness of ODEs
abstract: It is argued that even for a linear system of ODEs with constant coefficients, stiffness cannot properly be characterized in terms of the eigenvalues of the Jacobian, because stiffness is a transient phenomenon whereas the significance of eigenvalues is asymptotic. Recent theory from the numerical solution of PDEs is adapted to show that a more appropriate characterization of stiffness can be based upon pseudospectra instead of spectra. Numerical experiments with an adaptive ODE solver illustrate these findings.

title: A Parallel Row Distributed Linear Algebra System (PRDLA Users' Guide)

abstract: The purpose of this system is to provide an easy-to-use et of basic parallel matrix manipulation subroutines, in C, for use on the Intel iPSC/860 hypercube. Most of the subroutines exhibit good performance, but not necessarily optimal. Users are welcome to use these subroutines as building blocks in their own codes, to modify if the situation warrants this, or just to study the implementation to help guide their own programming. The subroutines all operate under the assumption that matrices are distributed by row in a natural wrap mapping. That is, if we assume p processors, row 1 is mapped to processor 0, row 2 is mapped to processor 1, row p is mapped to processor p-1, row p+1 is mapped to processor 0, etc. If this is deemed to restrictive, the user is welcome to use these codes as a starting point and develop their own codes (perhaps under less restrictive assumptions). The codes are not directly portable to other computer systems. However, the codes do use PICL (the portable instrumented communication library, developed at Oak Ridge National Laboratory); therefore, provided PICL is available the codes are easily ported.

title: Advantages of Differential Dynamic Programming Over Newton's Method for Discrete-time Optimal Control Problems
abstract: Differential Dynamic Programming (DDP) and stagewise Newton's method are both quadratically convergent algorithms for solving discrete time optimal control problems. Although these two algorithms share many theoretical similarities, they demonstrate significantly different numerical performance. In this paper, we will compare and analyze these two algorithms in detail and derive another quadratically convergent algorithm which is a combination of the DDP algorithm and Newton's method. This new second-order algorithm plays a key role in the explanation of the numerical differences between the DDP algorithm and Newton's method. The detailed algorithmic and structural differences for these three algorithms and their impact on numerical performance will be discussed and explored. Two test problems with various dimensions solved by these three algorithms will be presented. One nonlinear test problem demonstrates that the DDP algorithm can be as much as 28 times faster than the stagewise Newton's method. The numerical comparsion indicates that the DDP algorithm is numerically superior to the stagewise Newton's method.

title: A Singular Loop Transformation Framework Based on Non-singular Matrices
abstract: In this paper, we discuss a loop transformation framework that is based on integer non-singular

matrices. The transformations included in this framework are called A-transformations and include permutation, skewing and reversal, as well as transformation called loop scaling. This framework is more general than existing ones; however, it is also more difficult to generate code in our framework. This paper shows how integer lattice theory can be used to generate efficient code. An added advantage of our framework over existing ones is that there is a simple completion algorithm which, given a partial transformation matrix, produces a full transformation matrix that satisfies all dependencies. This completion procedure has applications in parallelization and in the generation of code for NUMA machines.

title: Access Normalization: Loop Restructuring for NUMA Compilers
abstract: A common feature of many scalable parallel machines is non-uniform memory access - a processor can access data in its local memory ten to a thousand times faster than it can access local data. In addition, when a number of remote accesses must be made, it is usually more efficient to use block transfers of data rather than to use many small messages. To run well on such machines, software must exploit these features. We believe it is too onerous for a programmer to do this by hand, so we have been exploring the use of restructuring compiler technology for this purpose. In this paper, we start with a language like FORTRAN-D with user-specified data distributions and develop a systematic loop transformation strategy called access normalization that restructures loop nests to exploit both locality and block transfers whenever possible. We demonstrate the power of our techniques using routines from the BLAS (Basic Linear Algebra Subprograms) library. Our loop transformation strategy is expressed in the framework of invertible matrcies and integer lattice theory, and it is an important generalization of Banerjee's framework of unimodular matrices.

title: Quality Mesh Generation in Three Dimensions
abstract: We show how to triangulate a three dimensional polyhedral region with holes. Our triangulation is optimal in the following two senses. First, our triangulation achieves the best possible aspect ratio up to a constant. Second, for any other triangulation of the same region into m triangles with bounded aspect ratio, our triangu- lation has size n=O(m). Such a triangulation is desired as an initial mesh for a finite element mesh refinement algorithm. Previous three dimensional triangulation schemes either worked only on a restricted class of input, or did not guarantee well shaped tetra- hedra, or were not able to bound the output size. We build on some of the ideas presented in previous work by Bern, Eppstein, and Gilbert, who have shown how to triangulate a two dimensional polyhedral region with holes, with similar quality and optimality bounds.

title: Stable Numerical Algorithms for Equilibrium
abstract: An equilibrium system (also known as a KKT system, a saddle- point system, or a sparse tableau) is a square linear system with a certain structure. G. Strang has observed that equilibrium systems arise in optimization, finite elements, structural analysis, and electrical networks. Recently, G.W. Stewart established a norm bound for a type of equilibrium system in the case that the "stiff- ness" portion of the system is very ill-conditioned. In this paper, we investigate the algorithmic implications of Stewart's result. We show that all standard textbook algorithms for equilibrium systems are unstable. Then we show that a certain hybrid method has the right stability property.

title: IPSC-MATLAB Reference Manual
abstract: IPSC-MATLAB is a programming environment for running MATLAB programs on the Intel iPSC/860 hypercube. The system is designed such that the user can execute computationally intensive poitions of MATLAB programs on the hypercube, whereas all other code is executed on a Sun-4 workstation (SPARCstation). The workstation acts as a remote host for the hypercube. MATLAB variables can migrate from the front-end (workstation) to the back-end (hypercube) and vice versa. IPSC-MATLAB combines the flexibility of MATLAB programming with the speed of the Intel hypercube.
Writing parallel programs in Fortran or C for the hypercube is a tedious task. Testing and debugging programs is difficult and time consuming. On the other hand, MATLAB, which runs on workstations, provides a convenient means of writing programs. However, because of the limited speed and memory of workstations, large problems cannot be solved. The hypercube is fast and has more memory. IPSC-MATLAB attempts to use the workstation as well as the hypercube to provide the user with a fast, flexible

environment for programming.

title: Advanced Computing Research Institute Semi-annual Research Activity Report, April 1992 - September 1992
abstract: The Advanced Computing Research Institute (ACRI) is a unit of the Cornell Theory Center and is affiliated with the Cornell Computer Science Department. The ACRI is concerned with research in scientific computation and its application to engineering and scientific problems. Of particular importance is the use of and potential of advanced computer architectures and environments. Research areas include parallelizing compilers for scientific computation and the design of algorithms for numerical linear algebra, optimization, and partial differential equations. Currently, ACRI researchers are collaborating on several large-scale applications in the computational sciences, including: protein-folding and related molecular chemistry problems, structural optimization and biomechanics, particle methods for turbulent combustion, discrete-control problems, and the application of boundary element methods. The parallel computers available to the ACRI for research include the Theory Center machines - a 64-node KSR computer, an IBM ES/9000, a network of IBM RS/6000s, as well as Computer Science resources: an 8K CM-200, a 32-node Intel iPSC/860, and a 64-node BBN Butterfly. This report consists of two parts. The first part contains a short summary of the progress made in the last six months on each of the four main projects: parallelizing compilers, computational linear algebra, computational optimization, and numerical methods for partial differential equations. Included also are a list of ACRI researchers and their research interests, a list of technical reports produced in the last six months, and a list of ACRI seminars. In the second part we highlight one of the projects, the parallelizing compiler work, where we give a more detailed introduction into this area and sketch our novel approach.

title: Approximation with Kronecker Products
abstract: Let A be an m-by-n matrix with m=m1m2 and n=n1n2. We consider the problem of finding (mathematical formula omitted) so that (mathematical formula omitted) is minimized. This problem can be solved by computing the largest singular value and associated singular vectors of a permuted version of A. If A is symmetric, definite, non-negative, or banded, then the minimizing B and C are similarly structured. The idea of using Kronecker product preconditioners is briefly discussed.

title: On the Convergence of Reflective Newton Methods for Large-scale Nonlinear Minimization Subject to Bounds
abstract: We consider a new algorithm, a reflective Newton method, for the problem of minimizing a smooth nonlinear function of many variables, subject to upper and/or lower bounds on some of the variables. This approach generates strictly feasible iterates by following piecewise linear paths ("reflection" paths) to generate improved iterates. The reflective Newton approach does not require identification as an "activity set." In this report we establish that the reflective Newton approach is globally and quadratically convergent. Moreover, we develop a specific example of this general reflective path approach suitable for large-scale and sparse problems.

title: A Reflective Newton Method for Minimizing a Quadratic Function Subject to Bounds on Some of the Variables
abstract: We propose a new algorithm, a reflective Newton method, for the minimization of a quadratic function of many variables subject to upper and lower bounds on some of the variables. This method applies to a general (indefinite) quadratic function, for which a local minimizer subject to bounds is required, and is particularly suitable for the large-scale problem. Our new method exhibits strong convergence properties, global and quadratic convergence, and appears to have significant practical potential. Strictly feasible points are generated. Experimental results on moderately large and sparse problems support the claim of practicality for large-scale problems.

title: Isotropic Effective Energy Simulated Annealing Searches for Low Energy Molecular Cluster States
abstract: The search for low energy states of molecular clusters is associated with the study of molecular conformation and especially protein folding. This paper describes a new global minimization algorithm which is effective and efficient for finding low energy states and hence stable structures of molecular clusters. The algorithm combines simulated annealing with a class of effective energy functions which are transformed from the original energy function based on the theory of renormalization groups. The algorithm converges to low energy states asymptotically and is more efficient than a general simulated annealing method.

title: A New Direction in Hydrodynamic Stability: Beyond Eigenvalues
abstract: Fluid flows that are smooth at low speeds become unstable and then turbulent at higher speeds. This phenomenon has traditionally been investigated by linearizing the equations of flow and looking for

unstable eigenvalues of the linearized problem, but the results agree poorly in many cases with experiments. Nevertheless, it has become clear in recent years that linear effects play a central role in hydrodynamic instability. A reconciliation of these findings with the traditional analysis can be obtained by considering the "pseudospectra" of the linearized problem, which reveal that small perturbations to the smooth flow in the form of streamwise vortices may be amplified by factors on the order of 10**5 by a linear mechanism, even though all the eigenmodes are stable. The same principles apply also to other problems in the mathematical sciences that involve non-orthogonal eigenfunctions.

title: Complexity Issues in Global Optimization: A Survey
abstract: Complexity theory refers to the asymptotic analysis of problems and algorithms. How efficient is an algorithm for a particular optimization problem, as the number of variables gets large? Are there problems for which no efficient algorithm exists? These are the questions that complexity theory attempts to address. The theory originated in work by Hartmanis and Stearns (1965). By now there is much known about complexity issues in nonlinear optimization. In particular, our recent book Vavasis (1991) contains all the details on many of the results surveyed in this chapter. We begin the discussion with a look at convex problems in the next section. These problems generally have efficient algorithms. In Section 3 we study the complexity of two nonconvex problems that also have efficient algorithms because of special structure. In Section 4, we look into hardness results (proofs of the nonexistence of efficient algorithms) for general nonconvex problems. Finally, in Section 5 we look at recent developments in "approximation" algorithms. We follow the notation in this chapter that lower-case boldface letters are vectors, lower-case italic letters are scalars, and upper-case italic letters are sets or matrices. Superscript T indicates matrix transpose, and aTx indicates inner product. The operators 'less than' and 'greater than' are applied component- wise to vectors; we say x is greater than y if each entry of x is greater than or equal to the corresponding entry of y.

title: Preconditioning Legendre Spectral Collocation Approximations to Elliptic Problems
abstract: This work deals with the H(exp 1) condition numbers and the distribution of the Beta~(sub N,M)-singular values of the preconditioned operators{Beta~(exp -1) (sub N,M) W(sub N,M) A^(sub N,M)}. A^(sub N,M) is the matrix representation of the Legendre Spectral Collocation discretization of the elliptic operator "A" defined by A(sub u) := -delta(u) + alpha(sub 1)u(sub x) + alpha(sub 2)u(sub y) + alpha(sub 0)u in omega (the unit square) with boundary conditions: u = 0 on Gamma(sub 0), delta(sub u) divided by delta(mu sub A) = alpha(u) on Gamma(sub 1). Beta~(sub N,M) is the stiffness matrix associated with the finite element discretization of the positive definite elliptic operator "B" defined by B(v) := -Delta(v) + b(sub 0i)v in omega with boundary conditions v = 0 on Gamma(sub 0), delta(v) divided by delta(mu sub B) = B(v) on Gamma(sub 1). The finite element space is either the space of continuous functions which are bilinear on the rectangles determined by the Legendre-Gauss-Lobatto (LGL) points or the space of continuous functions which are linear on a triangulation of omega determined by the LGL points. W(sub N,M) is the matrix of quadrature weights. When A = B we obtain results on the eigenvalues of Beta~(exp -1)(sub N,M) W(sub N,M) B^(sub N,M). We show that there is an integer N(sub 0) and constants alpha,beta with 0 less than alpha less than beta, such that: if min(N,M) gretaer than or equal to N(sub 0),i then all the Beta~(sub N,M)-singular values of Beta~(exp -1)(sub N,M) W(sub N,M) A^(sub N,M) lie in the interval [alpha,beta].Moreover, there is a smaller

interval, [alpha(sub 0), beta(sub 0)], independent of the operator "A", such that: if min(N,M) greatre than or equal to N(sub 0), then all but a fixed finite number of the Beta~(sub N,M)-singular value lie in [alpha(sub 0),beta(sub 0)]. These results are related to results of Manteuffel and Parter [MP]Parter and Wong [PW] and Wong [W1], [W2] for finite element discretizations.

title: Update on Tools for Parallel Programming at the CNSF
abstract: Not many CNSF users undertake the arduous task of parallelizing their programs. Of course, training, education, and available hardware will have a lot to do with changing this situation, but we feel that tools also have an important role to play. In 1989, we wrote: "At the present time, the general lack of parallel programming tools is an inhibitor to parallel programming at the Cornell National Supercomputer Facility (CNSF). The Technology Integration Group (TIG)is evaluating a number of tools designed to make parallel programming easier, including tools for source analysis, program development and execution analysis. The more effective tools will be 'mainstreamed', i.e. turned over to users, integrated into workshops and consulted on by staff." This provides an update to that status report. The major section ofthis paper describes Tools for Parallel Programming, divided into 12 categories. Each category is summarized in pretty much the same way as in 1989, and then new status and prospects are discussed. The paper concludes with some comments on hybrid program development systems andthe workstation environment. The appendices contain a table of all the tools and list acronyms, names, and institutions.

title: A Suite of Software Tools for Managing a Large Parallel Programming Project
abstract: A suite of software tools is presented for managing a large parallel programming project. The tools were selected recognizing that parallel program development is an iterative process and subject to mistakes and that software tools can be useful for maintaining source code flexibility and portability, tracking revisions, and analyzing variable usage and loop structure within a program. The tools discussed are: make, cpp, RCS, and FORGE 90. The concept of a toy program is introduced as a means for experimenting with a simpler version of an application program. Finally, the use of these tools and techniques is demonstrated as part of an optimization and parallelization effort for a scientific application program called ZELIG.

title: A Parallel Build-up Algorithm for Global Energy Minimizations of Molecular Clusters Using Effective Energy Simulated Annealing
abstract: This work studies the build-up method for the global minimizationproblem for molecular conformation, especially protein folding. The problem is hard to solve for large molecules using general minimization approaches because of the enormous amount of required computation. We therefore propose a build-up process to systematically "construct" the optimal molecular structures. A prototype algorithm is designed using the anisotropic effective energy simulated annealing method at each build-up stage. The algorithm has been implemented on the InteliPSC/860 parallel computer, and tested with the Lennard-Jones microcluster conformation problem. The experiments showed that the algorithm was effective for relatively large test problems, and also very suitable for massively parallel computation. In particular, for the 72-atom Lennard-Jones microcluster, the algorithm found a structure whose energy is lower than any others found in previous studies.

title: Magnetoconvection Dynamics in a Stratified Layer. I. 2D Simulations and Visualization (Revised 10/93)
abstract: To gain insight into the problem of fluid convection below the solar photosphere, time-dependent magnetohydrodynamic convection is studied by numerical simulation of the magneto-anelastic equations, a model appropriate for low Mach numbers. Numerical solutions to the equations are generated on a two-dimensional Cartesian mesh by a finite-difference, predictor-corrector algorithm. The thermodynamic properties of the fluid are held constant at the rigid, stress-free top and bottom boundaries of the computational box, while lateral boundaries are treated as periodic. In most runs the background polytropic fluid configuration is held fixed at Rayleigh number R=5.44 times the critical value, Prandtl number P=1.8, and aspect ratio a=1, while the magnetic parameters are allowed to vary. The resulting dynamical behavior is shown to be strongly influenced by a horizontal magnetic field which is imposed at the bottom boundary. As the field strength increases from zero, an initially unsteady "single-roll" state, featuring complex time dependence, is replaced by a steady "traveling-wave" tilted state; then, an oscillatory or "sloshing" state; then, a steady two-roll state with no tilting; and finally, a stationary state. Because the magnetic field is matched onto a potential field at the top boundary, it can penetrate into the nonconducting region above. By varying the magnetic diffusivity, the concentrations of weak magnetic fields at the top of these flows can be shown to be explainable in terms of an advection-diffusion balance.

title: Modeling the Landscape as a Dynamic Mosaic of Patches: Some Computational Aspects
abstract: The only thing that is certain about Nature is its patchiness. Patchiness is ubiquitous, occurring across systems, organizational levels, and spatio-temporal scales. Traditional modeling approaches in ecology often fail to recognize spatial patchiness because they usually assume spatial homogeneity. A landscape may be viewed as a hierarchical mosaic system of patches that are different in their age, size, shape, content, and other aspects. The spatial change of the patch mosaic results in the landscape pattern, whereas the phase change of individual patches at the local scale and temporal change in patch mosaics at larger scales gives rise to the landscape dynamics. Following such a patch dynamics conceptualization, a spatially explicit patch dynamic modeling approach has been developed based on a serpentine annual grassland. The model has two basic submodels: a spatially-explicit, age/size- structured patch demographic model and a multi-specific plant population dynamic model of a non-equilibrium island biogeographic type. In this paper, the basic structure and some computational aspects of the model are discussed.

title: The Effective Energy Transformation Scheme as a General Continuation Approach to Global Optimization with Application to Molecular Conformation
abstract: This paper discusses a generalization of the special function transformation scheme for global minimization for molecular conformation used in [3,4,14,15]. Theories for the method as a general continuation approach are established. We show that the method can transform an onlinear objective function into a class of gradually deformed, but "smoother", functions. An optimization procedure can then be applied to the new functions successively, to trace the solution back to theoriginal function. Two types of transformation are defined: the isotropic and the anisotropic. We show that both, although not applicable numerically to arbitrary functions because of the required high dimensional integration, can be applied to a large class of nonlinear partially separable functions, and, in particular, the energy functions for molecular conformation. Methods to compute exactly the required transformations are given. Advantages of this transformation approach over the conventional homotopy methods also are discussed.

title: An Efficient Trust Region Method for Unconstrained Discrete-Time Optimal Control Problems
abstract: Discrete-time optimal control (DTOC) problems are large-scaleoptimization problems with a dynamic structure. In previous work this structure has been exploited to provide very fast and efficient local procedures. Two examples are the differential dynamic programming algorithm (DDP) and the stagewise Newton procedure - both require only O(N) operations per iteration, where N is the number of time steps. Both exhibit a quadratic convergence rate. However, most algorithms in this category do not have a satisfactory global convergence strategy. The most popular global strategy is shifting: this sometimes works poorly due to the lack of automatic adjustment to the shifting element. In this paper we propose a method that incorporates the trust region idea with the local stagewise Newton's method. This method possesses advantages of both the trust region idea and the stagewise Newton's method, i.e., our proposed method has strong global and local convergence properties yet remains economical. Preliminary numerical results are presented to illustrate the behavior of the proposed algorithm. We also collect in the Appendix some DTOC problems that have appeared in the literature.

title: Parallel Structural Optimization Applied to Bone Remodeling on Distributed Memory Machines
abstract: This paper demonstrates parallel structural optimization methods on distributed memory MIMD machines. We have restricted ourselves to the simpler case of minimizing a multivariate non-linear function subject to bounds on the independent variables, when the objective function is expensive to evaluate as compared to the linear algebra portion of the optimization. This is the case in structural applications, when a large three-dimensional finite element mesh is used to model the structure. This paper demonstrates how parallelism can be exploited during the function and gradient computation as well as the optimization iterations. For the finite element analysis, a 'torus-wrapped' skyline solver is used. The reflective Newton method which attempts to reduce the number of iterations at the expense of more linear algebra per iteration is compared with the more conventional active set method. All code is developed for an Intel iPSC/860, but it can be ported to other distributed memory machines. The methods developed are applied to problems in bone remodeling. In the area of biomechanics, optimization models can be used to predict changes in the distribution of material properties in bone due to the presence of an artificial implant. The model we have used minimizes a linear combination of the mass and strain energy in the entire domain subject to bounds on the densities in each finite element. Early results show that the early reflective Newton method can outperform active set methods when a significant number of variables are not active at the minimum.

title: An Accelerated Interior Point Method Whose Running Time Depends Only on A
abstract: We propose a "layered-step" interior point (LIP) algorithm for linear programming. This algorithm follows the central path, either with shortsteps or with a new type of step called a "layered least squares" (LLS) step. The algorithm returns the exact global minimum after a finite numberof steps - in particular, after O (mathematical symbol omitted) iterations, where c(A) is a function of the coefficient matrix. The LLS steps can be thought of as accelerating a path-following interior point method whenever near-degeneracies occur. One consequence of the new method is a new characterization of the central path: we show that it composed of at most n-squared alternating straight and curved segments. If the LIP algorithm is applied to integer data, we get as another corollary a new proof of a well-known theorom by Tardos that linear programming can be solved in strongly polynomial time provided that A contains small-integerentries.

title: Pseudospectra of the Wave Operator with an Absorbing Boundary
abstract: For systems which can be described by u(sub t) = Au with a highly non-normal matrix or operator A, the spectrum of A may describe the behavior of the system poorly. One such operator arises from the one-dimensional wave equation on a finite interval with a homogeneous Dirichlet condition at one end and a linear damping condition at the other. In this paper the pseudospectra (norm of the resolvent) of this operator are computed in an energy norm, using analytical techniques and computations with discrete approximations. When the damping condition is perfectly absorbing, the pseudospectra are half-planes parallel to the imaginary axis, and in other cases they are periodic in the imaginary direction and approximate strips of finite thickness. The non-normality of the operator is related to the behavior of the system and the limitations of spectral analysis.

title: Some Efficient Algorithms for Unconstrained Discrete-time Optimal Control Problems
abstract: The differential dynamic programming algorithm (DDP)and the stagewise Newton procedure are two typical examples of efficient local procedures for discrete-timeoptimal control (DTOC) problems. It is desirable to generalize these local procedures to globally convergent methods. One successful globalization was recently proposed by Coleman and Liao [3] which combines the trust region idea with Pantoja's stagewise

Newton procedure. In this paper, we propose several algorithms for DTOC problems which combine a modified "dogleg" algorithm with DDP or Pantoja's Newton procedure. These algorithms possess advantages of both the dogleg algorithm and the DDP or the stagewise procedure, i.e.,they have strong global and local convergence properties yet remain economical. Numerical results are presentedto compare these algorithms and the Coleman-Liao algorithm.

title: Experiments in the Concurrent Computation of Spatial Association on the KSR1
abstract: Spatial association measures, when computed for large data sets, have significant computational requirements. Parallel processing is one way to address these requirements. The design of parallel programs, however, requires careful planning since many factors under programmer control affect the efficiency of the resulting computations. In this paper, two strategies of parallel processing are described using as an illustration a measure of spatial association, G(d). An evaluation is made of the efficiency of the parallel implementations by varying the problem size and the number of processors used in parallel. The results obtained indicate that parallel processing can currently enable analysts to work in near-real-time with problems that range in the tens of thousands of observations; such problems require less than two minutes of execution time on the KSR1. Also super linear speed ups of almost 1500 are obtained for the computation phase of the problem.

title: An Efficient Linear Scaling Algorithm for Tight Bonding Molecular Dynamics
abstract: A novel formulation for tight binding total energy calculations and tight binding molecular dynamics, which scales linearily with the size of the system, is presented. The linear complexity allows us to treat systems of very large size and the algorithm is already faster than the best implementation of classical diagonalization for systems of 64 atoms. In addition, it is naturally parallelizable and it permits us therefore to perform molecular dynamics simulations of systems of unprecedented size. Finite electronic temperatures can also be taken into account. We illustrate this method by investigating structural and dynamical properties of solid and liquid carbon at different densities.

title: Fast Wavelet Transforms for Matrices Arising from Boundary Element Methods
abstract: (The following contains mathematical formulae and symbols that may become distorted in ASCII text.) For many boundary element methods applied to Laplace's equation in two dimensions, the resulting integral equation has both an integral with a logarithmic kernel and an integral with a discontinuous kernel. If standard collocation methods are used to discretize the integral equation we are left with two dense matrices. We consider expressing these matrices in terms of wavelet bases with compact support via a fast wavelet transform as in Beylkin, Coifman, and Rokhlin. Upper bounds on the size of the wavelet transform elements are obtained. These bounds are then used to show that if the original matrices are of the size N x N, the resulting transformed matrices are sparse, having only O(N log N) significant entries. Some numerical results will also be presented. Unlike Beylkin, Coifman and Rokhlin who use the fast wavelet transform as a numerical approximation to a continuous operator already expressed in a full wavelet basis of L2(IR), we think

of the fast wavelet transform as a change of basis matrix for a finite dimension, and apply it to a discretized function or matrix. As a result, we can use this fast wavelet transform as a "black box" transformation in existing boundary element codes.

title: Parallel Continuation-Based Global Optimization for Molecular Conformation and Protein Folding
abstract: This paper presents our recent work on developing parallel algorithms and software for solving the global minimization problem for molecular conformation, especially protein folding. Global minimization problems are difficult to solve when the objective functions have many local minimizers, such as the energy functionsfor protein folding. In our approach, to avoid directly minimizing a "difficult" function, a special integral transformation is introduced to transform the function into a class of gradually deformed, but "smoother" or "easier" functions. An optimization procedure is then applied to the new functions successively, to trace their solutions back to the original function. The method can be applied to a large class of nonlinear partially separable functions including energy functions for molecular conformation and protein folding. Mathematical theory for the method, as a special continuation approach to global optimization, is established. Algorithms with different solutions tracing strategies are developed. Different levels of parallelism are exploited for the implementation of the algorithms on massively parallel architectures.

title: Exploitation of Latency Hiding on the KSR1 - Case Study: The Barnes Hut Algorithm
abstract: This study is aimed at examining the performance of dynamic, irregular and loosely synchronous class of applications on the KSR1 distributed shared memory COMA system. The Barnes-Hut tree based algorithm for simulating galactic evolution [1], was chosen as a representative of this class of applications. The performance measures include the overall time-stepping loop execution time, the efficacy of the scaling rules (EES and RCTS) proposed in [2] as well as the computational load balance achieved by the CostZone data partitioning scheme [1] under these scaling rules. We define notions of geographical locality, transfer locality flux and partition locality flux to explain the sources of remote memory accesses in the application. The contributions of our study include two runtime latency hiding techniques PST and PREFH proposed for the effective and automatic utilization of the poststore and prefetch instructions to hide the latencies of remote memory accesses. The architectural support assumed, compiler analysis required and code instrumentation schemes for the implementation of the PST and PREFH techniques are presented in this paper. We also examine the scalability of our schemes under the afore mentioned scaling rules. These schemes were tuned for a 32k particle simulation size on a 112 processor configuration, producing a reduction of 30% in the overall loop execution time of the simulation. Further, a combination of the schemes, PREPST, produced an overall reduction of 50% in the loop execution time of simulation. These improvements were traced to a reduction in the problems of locality fluxes which arose as the application was scaled under the EES and RCTS rules/ Interestingly, the problems of locality fluxes manifested themselves as load imbalance conditions in the application. We found that our schemes did not scale too well under EES scaling, but produced appreciable reductions in execution timings under RCTS scaling. It needs to be emphasized that our work involved the study of a whole application and on a 128 processor KSR1 machine, as opposed to most other work reported to date which examine performances of computational kernels on 32 or 64 processor configurations only.

title: Rate Equations for the Growth of Cu Islands on Cu(001)
abstract: The kinetics of island nucleation and growth during deposition of Cu atoms on Cu(001) is studied using rate equations. The equations are derived using microscopic calculations of the energy landscape on the surface, previously used in Monte Carl (MC) simulations. This allows a quantitative comparison between the rate equations and the MC results. Our rate equations take into account atoms that fall on the bare substrate as well as on top of existing islands, the mobility of single atoms and small islands, the coalescence of adjacent islands and the possible separation of atoms from island edges. The rate equations are used to explore the island size distribution and island density as a function of the coverage and deposition rates. These rate equations provide a useful and flexible tool that allows to easily modify particular microscopic properties of the system such as the mobility of small islands or the rate of coalescence and examine their effect while leaving all other features intact.

title: The Integration of ParaScope and Lambda
abstract: We have been experimenting with combining three powerful language tools for large, scientific, parallel Fortran codes. One tool is ParaScope, a programming envirnment; another tool is the Lambda Toolkit, a collection of routines for performing loop transformations using invertible matrices; the third is FORGE 90, a collection of tools for parallelizing Fortran programs. Initial sucess with incorporating the Lambda Toolkit into ParaScope led us to undertake the work leading to a new program preparation strategy, in which one first uses a modified ParaScope to perform DataAccess Normalization, then uses FORGE 90 to produce a parallel program for a distributed memory platform. We describe the details of this strategy and present some performance results for the IBM SP1. We conclude that the combination of ParaScope and the Lambda Toolkit (called “ped-Lambda”) is a useful transformation tool.

title: Optimization and Parallelization of a Commodity Trade Model for the SP1, Using Parallel Programming Tools
abstract: We compare two different approaches to parallelization of Fortran programs. The first approach

is to optimize the serial code so that it runs as fast as possible on a single processor, and then optimize the parallel version. In this paper a variety of parallel programming tools is used to obtain an optimal, parallel version of an economic policy modelling application for the IBM SP1. We apply a new technique called Data Access Normalization; we use an extended ParaScope as our parallel programming environment; we use FORGE 90 as our parallelizer; and we use KAP as our optimizer. We make a number of observations about the effectiveness of these tools. Both strategies obtain a working, parallel program, but use different tools to get there. On this occasion, both KAP and Data Access Normalization lead to the same critical transformation of inverting four of the twelve loop nests in the original program. The next most important optimization is parallel I/O, one of the few transformations that had to be done by hand. Speedups are obtained on the SP1 (using MPLp communication over the High Speed Switch).

title: Tight Binding Molecular Dynamics on Parallel Computers
abstract: With a new and intrinsically parallel algorithm for Tight Binding Molecular Dynamics we obtain a performance of 3.4 Gigaflops per million dollar on a cluster of 8 Hewlett Packard workstations in a simulation of 216 Silicon atoms. One time step with this new algorithm takes as much time for the 216 atom system as one time step with a conventional algorithm on a NEC-SX3 supercomputer. In addition, the linear scaling of new algorithm allows us to calculate systems of unprecendented size which are not any more accessible by the combination of standard algorithms and vector supercomputers.

title: Parallel Multifrontal Solution of Sparse Linear Least Squares Problems on Distributed-memory Multiprocessors
abstract: We describe the issues involved in the design and implementation of efficient parallel algorithms for solving sparse linear least squares problems on distributed-memory multiprocessors. We consider both the QR factorization method due to Golub and the method of corrected semi-normal equations due to Bjorck. The major tasks involved are sparse QR factorization, sparse triangular solution and sparse matrix-vector multiplication. The sparse QR factorization is accomplished by a parallel multifrontal scheme recently introduced. New parallel algorithms for solving the related sparse triangular systems and for performing sparse matrix-vector multiplications are proposed. The arithmetic and communication complexities of our algorithms on regular grid problems are presented. Experimental results on an Intel iPSC/860 machine are described.

title: All-Electron Study of Gradient Corrections to the Local Density Functional in Metallic Systems
abstract: Using the all-electron Linearized Augmented Plane Wave (LAPW) method, we calculate the effect of including gradient corrections to the exchange correlation functional on the structural properties of the simple metal Al, transition metals Ta, W, Pt, and noble metals Cu, Ag, Au. For all the systems studied, the local density approximation (LDA) yields bond-lengths that are too short and bulk moduli that are too large. The generalized gradient functional introduced by Perdew and Wang (PW91) yields corrections that are in the right direction (larger bond-lengths and smaller bulk moduli), but it frequently over compensates, particularly for the heavier elements. The PW 91 functional predicts the lattice constant and bulk modulus of Al and Cu more accurately than the LDA but yields values thatare less accurate than the LDA for W, Pt, Au.

title: A New Parallel Algorithm for Global Optimization with Application to the Molecular Cluster Problem
abstract: In this paper we present a simple algorithm for global optimization. This algorithm combines random searches with efficient local minimization algorithms. The proposed algorithm begins with an initial "local minimizer." In each iteration, a search direction is generated randomly, along which some points are chosen as the initial points for the local optimization algorithm and several "local minimizers" are obtained. The next iteration is determined by comparing these localminimizers. We will discuss the expected number of iterations for finding a global minimizer with this algorithm. Several variants of the algorithm that take advantage of the partially separable structure are proposed for the Lennard-Jones cluster problem and tested on the IBM SP1 parallel computer. Our numerical results show that our algorithms are promising.

title: Pull the Weighted Center Towards the Solution of LP
abstract: In the paper of Liao and Todd [3] two weighted centers are introduced and used to design algorithms for solving systems of linear inequalities. The linear programming problems can be solved via the weighted

centers of a sequence of linear inequalities formed by letting the objective be an extra constraint and increasing the lower bound corresponding to the objective function as long as it is possible. In this paper we study the second kind of weighted center of [3] which ismore computationally oriented and show that, under a regularity assumption, the weighted center of the linear inequality with the objective as an extra constraint converges to the solution of the linear programming problem under consideration as the upper bound corresponding to the objective function is pulled towards the infinity. We propose a relaxed version of one of the algorithms of [3]. This modified version does not try to find an accurate center during each iteration; instead, an approximate center which is the k-th feasible iterate is determined in the k-th iteration. We show that this modified algorithm finds an e-solution in finity many iterations. Some limited numerical results are presented to compare our algorithm with the simplex method and indicate that our algorithm is promising.

title: Advanced Computing Research Institute Annual Research Activity Report September 1993 - September 1994
abstract: The Advanced Computing Research Institute (ACRI) is a unit of the Cornell Theory Center and is affiliated with the Cornell Computer Science Department. The ACRI is concerned with research in scientific computation and its application to engineering and scientific problems with the emphasis on the use and potential of advanced computer architecture and environments. Research areas include restructuring compilers for scientific computation, and the design of algorithms for numerical linear algebra, optimization, and differential equations. Currently, ACRI researchers are collaborating on several large-scale applications in the computational sciences, including: protein-folding and related molecular chemistry problems, structural optimization and biomechanics, particle methods for turbulent combustion, discrete-control problems, and the application of boundary elementmethods. The parallel computers available to ACRI for research include the Theory Center machines - a 128-node KSR computer, a 64-node IBM SP, and a network of IBM RS/6000s. This report contains a short summary of the progress made in the last year on each of the four main projects: parallelizing compilers, computational linear algebra, computational optimization, and numerical methods for partial differential equations. Included also are a list of ACRI researchers and their research interests, a list of technical reports produced this last year, and a list of ACRI seminars.

title: Slip Complexity in a Crustal-Plane Model of an Earthquake Fault
abstract: We study numerically the behavior of a two-dimensional elastic plate (acrustal plane) that terminates along one of its edges at a homogeneous fault boundary. Slip-weakening friction at the boundary, inertial dynamics in the bulk, and uniform slow loading via elastic coupling to a substrate combine to produce a complex, deterministically chaotic sequence of slipping events. We observe a power-law distribution of small to moderately large events and an excess of very large events. For the smaller events, the moments scale with the rupture length in a manner that is consistent with seismological observations. For the largest events, rupture occurs in the form of narrow propagating pulses.

title: On Global Convergence of a Trust Region and Affine Scaling Method for Nonlinearly Constrained Minimization
abstract: (The following contains mathematical formulae and symbols that may become distorted in ASCII text.) A nonlinearly constrained optimization problem can be solved by the exact penalty approach involving non differentiable functions (summation(i)of |ci(x)|) and (summation(i) of max(0,ci(x))). In [11], a trust region affine scaling approach based on a 2-norm subproblem is proposed for solving a nonlinear l 1 problem. The (quadratic) approximation and the trust region subproblem are defined using affine scaling techniques. Explicit sufficient decrease conditions are proposed to obtain a limitpoint satisfying complementarity, dual feasibility, and second order optimality. In this paper, we present the global convergence properties of this new approach.

title: An Affine Scaling Algorithm for Minimizing Total Variation in Image Enhancement
abstract: A computational algorithm is proposed for image enhancement based on total variation minimization with constraints. This constrained minimization problem is introduced by Rudin et al [13,14,15] to enhance blurred and noisy images. Our computational algorithm solves the constrained minimization problem directly by adapting the affine scaling method for the unconstrained l 1 problem [3]. The resulting computational

scheme, when viewed as an image enhancement process, has the feature that it can be used in an interactive manner in situations where knowledge of the noise level is either unavailable or unreliable. This computational algorithm can be implemented with a conjugate gradient method. It is further demonstrated that the interactive enhancement process is efficient.

title: ARCH, An Object-Oriented Library for Asynchronous and Loosely Synchronous System Programming
abstract: ARCH is a C++-based library for asynchronous and loosely synchronous system programming. The current version offers a set of programming constructs that are outlined below:*** Threads: The construct is presented as a class from which the user can derive his own classes. The class encapsulates a small set of status variables and offers a set of functions for declaration, initialization, scheduling, priority setting, yielding and stopping.*** Processes: A process is a more regular and structured programming construct whose scheduling and termination obey additional synchronization rules. Together with the synchronous point-to-point communication system offered in the library (see below), processes favor a parallel programming style similar to OCCAM's (actually, an extension of it that removes most static features and allows processes to share data). The semantics of this model is well understood and will undoubtedly facilitate the development of correct large asynchronous code. The library has been designed so that the C++ compiler is able to check the static semantics of programs (complete type checking, send-recv correct matching, ...).*** Synchronous communication: Threads and processes synchronize and communicate via communication channels. There are four types of communication channels for local or remote synchronization or synchronous point-to-point communication. Inter-processor channels are essentially tools for building virtual topologies. The channel classes offer functions to send to or receive from a channel and get the size of the latest received message. More specialized synchronization-communication tools can be derived from channels.*** Global data and pointers: Beside threads, the library offers basic tools for developing distributed data abstractions. Global data are data that can be defined at given locations in the distributed memory but are visible from all processors. Global pointers are a generalization of C++ pointers that allow for addressing global data at any place over the distributed memory. As usual pointers, global pointers are subjected to arithmetic and logic manipulations (incrementation, dereferencing, indexing, comparision...). The library provides basic operators for global data and pointer definition.*** Global read/write functions: Global pointer expressions provide global references over the distributed memory that can subsequently be used asarguments to global read/write functions. These functions allow the processors to get access to all global data regardless of their locations over the distributed memory. In their most complete form, the read/write functions operate as remote procedure calls. At the programmer's level, global read/write functions appear as "one-sided": a read/write operationis executed on the processor that needs to read/write global data but need not be explicitly handled by the processor associated to the memory holding the data.*** Spread and remote Arrays. Two basic distributed data structures have been built in the library. Spread arrays are arrays that have some of their dimensions spread over the distributed memory according to a given policy. Remote arrays are arrays that are defined at a given place in the distributed memory but can be accessed from any other. The spread and remote array classes (SpreadArray and RemoteArray) provide functions for global reference calculation. Global references can subsequently be used as arguments to global read/write functions. One can specialize global pointers to operate on spread or remote arrays. The global pointer class (Star class) offers distinct arithmetic and logic operator sets for unassigned, spread and remote global pointers. The library encourages parallel code writing in a style that relies on the object-oriented approach: first, build the abstractions that the application at hand relies on; next, make an efficient implementation of the abstraction; and finally, develop

the application on top of them. The abstractions can be distributed data types derived from those built in the library (spread and remote arrays: see code of the segmentation algorithm provided with the library) or new distributed types built in the same way or types reused from other applications. This approach should favor parallel code production with many desirable properties such as efficiency, portability, reusability, ... The library uses MPI as a communication interface. The current implementation runs on the IBM-SP2. Two versions of the library have currently been released.The first one is based on the IBM C++ compiler and MPI library. The second one makes use of the GNU g++ compiler and the MPICH public domain version of MPI. Porting the latter to any parallel machine supporting these two software systems should be straightforward.

title: Tectonic evolution of the Atlas Mountains, North Africa
abstract: Copyright 1998, Weldon Beauchamp.
See also:
http://atlas.geo.cornell.edu/dissertations/Beauchamp_1998.htmThe Atlas Mountains of North Africa are one of the largest intracontinental mountain belts in the world. Despite the size of this orogen, the basic kinematic and tectonic evolution of the Atlas Mountains has previously not been well understood. These mountains formed hundreds of kilometers from active plate margins. The formation of the Atlas Mountains was greatly influenced by a previous Mesozoic intracontinental rift system. This rift system spanned half of the African continent and was larger in breadth than the Red Sea.
This study set out to synthesize existing data and studies of the Atlas Mountains and integrate these data with new geological, geophysical and remote sensing data. The construction of a tectonic map was undertaken to define the tectonic units and terraines of North Africa. The delineation of these regions allow for the study of how they have interacted during the kinematic evolution of the Atlas system.
Geological field work was undertaken to study the kinematics of inversion tectonics and to construct a balanced geological-geophysical transect. The transect suggests shortening across the orogen (36 km) was achieved by thrusting along detachments at several levels in the upper crust. Syn-rift and post-rift sedimentary rocks were uplifted by the reactivation of Synrift normal faults and newly formed thin-skinned thrust faults. A restoration of the deformed cross section indicates the original Atlas rift basin was approximately 113 kilometers wide.
Shortening across the High Atlas Mountains resulted in a partitioning of strain, with the greatest magnitude of shortening occurring along the margins of the High Atlas Mountains. The partitioning of strain may involve the transfer of shortening from the margins at shallow depths, to the mid-lower crust in the central region of the orogen. Thrusting in the High Atlas Mountains is bivergent, with thrusts dipping to the south along the northern margin, and northward dipping faults to the south.
The presence of preexisting structural geometries such as accommodation zones, fault ramps, fault relays and en echelon faulting formed by rift processes will have an effect on subsequent compressional stress fields generated by plate convergence and other tectonic processes. Superposed folding which is disharmonic may in fact be a unique characteristic to inverted rift systems that result in intracontinental mountain belts.

title: Lithospheric structure of the western United States and the Tibetan Plateau: Implications on their

mechanism of uplift
abstract: Copyright 1991, Mohammed Noureddine Beghoul. See also: http://atlas.geo.cornell.edu/dissertations/Beghoul_1991.htmThis dissertation seeks to determine the upper mantle structure and the mechanisms responsible for the Cenozoic uplift of the high terranes located near plate boundaries: the Tibetan Plateau and western North America. The upper mantle structure is determined using the first P arrivals obtained from the International Seismological Centre (ISC) at regional distances (2 - 22 degrees).

In the first chapter a methodology is presented for computing mantle lid Pn velocities using ISC data together with a detailed error analysis. Application of this algorithm to Colorado Plateau yields an average Pn velocity of 8.12 +/- 0.09 km/s. This value is higher than the one reported in the literature but similar to that beneath stable midcontinent regions. We use this Pn value and the Cenozoic history of the plateau to constrain the mode of uplift.

In chapter two, using the same techniques, we confirm the lower Pn velocity beneath the Basin and Range Province and show the presence of about 4% intrinsic azimuthal Pn velocity anisotropy in the mantle lid beneath the Basin and Range. The direction of high velocity coincides with the direction of present-day extension in the Basin and Range Province (i.e., NW - SE). We show that this anisotropy is the result of Cenozoic extension rather than a cumulative signature of older tectonic events.

In chapter three, a modified version of the algorithm and detailed mapping of Sn attenuation allow the determination of mantle lid thickness beneath the western United States and Tibet. We show that the mantle lid thickness beneath the southern 2/3 of Tibet ranges from 135-165 km thick. This value is similar to the one we find for the Great Plains.

The deep structure, Cenozoic uplift, and various other geophysical and geological data of these two high terranes are consistent with the subduction of flat slabs beneath them. The continental Indian Plate is still beneath the southern 2/3 of Tibet, but the oceanic Farallon Plate has already been delaminated from the overriding North American Plate.

title: Crustal evolution of the northern Arabian Platform beneath the Syrian Arab Republic
abstract: Copyright 1991, John Best. See also: http://atlas.geo.cornell.edu/dissertations/Best_1991.htmNewly released geological and geophysical data from the Syrian Arab Republic are used to document the geological history of the northern Arabian platform in the Middle East. The primary observation of this synthesis is the focusing of various phases of Phanerozoic deformation (Mesozoic rifting and Cenozoic transpression) along strike of a proposed Proterozoic suture that has acted as a long-lived zone of crustal weakness. This deformation zone is presently manifested by the intracontinental Palmyride mountain belt, an inverted rift, trending NE-SW through central Syria. The geological history recognized for the northern Arabian platform is similar in many respects to that of the southern Arabian platform, including: (1) Proterozoic convergence and cratonization, (2) minor Cambrian extension, (3) a relatively stable Paleozoic margin of Gondwanaland marked by predominantly clastic deposition, (4) eastward tilting of the Arabian plate in the Cenozoic. The important difference in the evolution of the northern platform from the southern platform occurs during the Mesozoic with the development of the Levantine margin in the eastern Mediterranean and the Palmyride rift in the continental interior.

The intracontinental Palmyride mountain belt is the result of Late Cretaceous-present inversion of the Palmyride rift. Reactivation of rift boundary faults occurred in response to transpressive movement along basement-controlled strike-slip faults. The belt is divided into three provinces based on changes in structural style: the south Palmyride fold belt characterized by narrow, en enchelon ridges, the Bishri, and Bilas blocks expressed as broad, antiformal structures. The mountain belt may be characterized by thin-skinned

deformation in the south fold belt and thick-skinned deformation in the northern and eastern provinces.

title: Balanced cross sections, seismic stratigraphy, and structural interpretation of the intracontinental Palmyride fold belt, Syria
abstract: Copyright 1991, Thomas Chaimov. See also: http://atlas.geo.cornell.edu/dissertations/Chaimov_1991.htmThe Palmyride fold belt in central Syria is the result of Late Mesozoic and Cenozoic inversion of a Late Paleozoic and Mesozoic intraplate trough located within the northern Arabian platform. Detailed analysis of available seismic reflection profiles from the Palmyrides reveals the Late Mesozoic to present transpressive structures of the Palmyrides and clarifies the timing and magnitude of such deformation within the belt. Uplift of the Mesozoic Palmyride trough began in the Late Cretaceous, rejuvenated in the Middle Eocene, and culminated in the period from the Miocene to present. Each of the three episodes of deformation was temporally associated with a distant (~300 km) Arabian plate margin tectonic event as follows: (1) Late Cretaceous collision between the northern and eastern margin of the Arabian plate and a microplate or island arc; (2) Middle Eocene incipient faulting of the Red Sea/Dead Sea fault system; and (3) Miocene to present shortening of the Arabian-Eurasian plate collision zone along the Bitlis/Zagros suture in Turkey and Iran.
Despite this repeated tectonism, only 20-25 km of shortening accumulated in the southwestern, most strongly deformed sector of the belt, diminishing to only a few kilometers 400 km along strike to the northeast. And although Triassic evaporites form local detachment surfaces, there has been no large-scale lateral transport of Mesozoic and Cenozoic rocks over Paleozoic rocks in the Palmyrides of Syria. Rather, deep structures in Paleozoic rocks appear to be in general concord with structures in overlying Mesozoic and Cenozoic rocks.

title: Late Cenozoic tectonics of the Middle Atlas Mountains, Morocco: Continental deformation in the diffuse western Mediterranean plate boundary
abstract: Copyright 1999, Francisco Gomez. See also: http://atlas.geo.cornell.edu/dissertations/Gomez_1999.htmThe Atlas Mountains of North Africa, located in the African foreland of the Alpine mountain belts, comprise a 2,000 km long Cenozoic mountain chain whose development was guided by older Mesozoic rift structures. This dissertation examines one component, the Middle Atlas Mountains of Morocco, using geological and geophysical data to constrain the tectonic development of the mountain chain. These results are then placed in the broader context of regional deformation. The NE-SW trending Middle Atlas Mountains are obliquely oriented within the late Cenozoic regional stress field, resulting in deformation partitioned into strike-slip faulting and thrust-related folding. Kinematic analyses of fault-slip data and earthquake focal mechanisms demonstrate that compressional deformation dominates the Folded Middle Atlas, whereas strike-slip faulting, with possible horizontal extension, predominates in the Tabular Middle Atlas. Geological field observations, digital topography, LANDSAT imagery, and seismicity provide evidence for recent tectonics in the Middle Atlas.
In the central Middle Atlas, cross-section balancing across the 20 km wide fold belt demonstrates about 4.7 km of Cenozoic horizontal shortening producing 800 m of structural relief. Other constraints on crustal thickening suggest a discrepancy between contraction and thickening. One possible explanation involves partitioning crustal deformation with depth: The upper crust shortens by thickening (faulting and folding),

whereas the lower crust deforms laterally.

At the northern extent of the mountain chain, the Guercif Basin developed where the Middle Atlas abut the Rif thrust belt. Similar timing of extensional deformation and proximity with the Rif, suggest that the Guercif Basin has been influenced by Rif tectonics. Stratal relations demonstrate that uplift of the Middle Atlas is a late Cenozoic phenomenon.

In Morocco, shortening of the High and Middle Atlas Mountains accommodated 20-45% of the total African-Eurasian plate convergence since the Early Miocene. The diffuse plate boundary comprises large, relatively rigid crustal blocks (Moroccan Meseta, High Plateau, and Saharan Platform) bounded by narrow deformable zones (the Atlas). In this context, the Middle Atlas can be interpreted as an accommodation zone resulting from differential movements between two large crustal blocks impinging on stable Africa. The Atlas Mountains exemplify the possible structural influence of inherited crustal weaknesses in a diffuse plate boundary such as the western Mediterranean region.

title: Seismicity and active tectonics of the Himalayas and Tibetan Plateau
abstract: Copyright 1984, James Ni. See also: http://atlas.geo.cornell.edu/dissertations/Ni_1984.htmAvailable geophysical and geological data are analyzed with additional new data to further the understanding of the fundamental tectonic processes involved in the Himalayan-Tibetan continental collision zone. Seismicity of the Himalayas suggests that at present the Indian Plate underthrusts the Himalayas as a coherent unit along a shallow detachment. The geometry of this detachment beneath the Lesser Himalayas is constrained by well data and well-determined focal depths of moderate-sized earthquakes. This detachment surface, at or near the top of the downgoing Indian plate, dips at approximately a 15 degree angle from about 10-km to 20-km depth. This result supports a model of the active tectonics of the Himalayas as "thin-skinned" and analogous to the Paleozoic tectonics of the southern Appalachian Collision Zone.

New seismological observations of velocities and propagation characteristics of Pn, Sn and Lg waves beneath the Himalaya-Tibet and surrounding region can be interpreted, although not uniquely, to indicate the shallow-angle underthrusting of the Indian continental lithosphere beneath the Tibetan Plateau. The most significant observation is that, except beneath the northern part, high-frequency Sn waves propagate efficiently in the uppermost mantle beneath the Tibetan Plateau. Strong attenuation of Sn waves suggests the existence of a low-Q zone in the uppermost mantle beneath northern Tibet.

Analysis of Landsat imagery and fault plane solutions of shallow crustal earthquakes in both the Tethyan Himalayas and Tibet indicate that normal faulting and east-west extension are the dominant mode of deformation occurring in the late Cenozoic time. The normal faulting is due to an east-west deviatoric tensional stress within the elevated Tethyan Himalayas and Tibet.

Seismicity combined with structural elements mapped from digitally processed Landsat 3 Multispectral Scanner (MSS) data provide valuable information about neotectonic processes in the overthrusting western Himalayan blocks. The rhomboidal-shaped upper Sutlej River Basin consists of many NNE-trending fault blocks and is interpreted as a pull-apart basin. This pull-apart basin is explained as a result of oblique underthrusting of the Indian plate beneath Himalayas-Tibet.

title: Lithospheric and upper mantle structure beneath northern Morocco and central Syria

abstract: Copyright 1995, Dogan Seber. See also: http://atlas.geo.cornell.edu/dissertations/Seber_1995.htmNorthern Morocco and central Syria accommodate two of the most significant intraplate mountain belts on earth: the Atlas Mountains (High and Middle) and the Palmyride mountains, respectively. In contrast to interplate mountain belts like the Rif mountains in northern Morocco, intraplate mountain belts develop away from any plate boundaries. Hence, their formation is more difficult to explain. In this dissertation, seismological data from a recently installed digital seismic network in Morocco along with other available datasets, such as Bouguer gravity, seismic reflection, and surface geology, are analyzed in order to map the three-dimensional structure of the lithosphere and upper mantle beneath northern Morocco. Seismic data are also used in explaining some aspects of earthquake hazards in Morocco. New geodynamic models are proposed for both the Atlas and Rif mountains of northern Morocco. Teleseismic tomography results show that the lithosphere beneath the Atlas mountains is relatively thinner as evidenced by slower velocity anomalies. In contrast, beneath the Rif mountains a relatively fast upper mantle velocities are observed. Isostatic gravity anomalies show that the central High Atlas has a thick (~45 km) and isostatically compensated crust, whereas the Middle Atlas with a crustal thickness of about 30 km is not compensated, and that they are probably dynamically supported. The spatial distribution of intermediate-depth seismicity, regional seismic waveform propagation characteristics, Bouguer gravity anomalies, seismic reflection and drill hole data as well as surface geology are used to argue that the lithosphere beneath the Rif region has delaminated and it is sinking into the asthenosphere. This ongoing delamination process is proposed to have formed the Rif and Betic mountain belts around the Alboran Sea.

The Palmyride intraplate mountain belt in central Syria, which shows a similar geologic history to the Atlas system of Morocco, is also studied. The upper part of the crust is mapped in central Syria beneath the Palmyrides fold-thrust belt and adjacent areas using very dense seismic refraction data. The results show that beneath the axis of the Palmyrides mountain belt a deep (~11 km) trough, formed in the Mesozoic, exists despite the Cenozoic inversion and uplift.

title: Complete Orthogonal Decomposition for Weighted Least Squares
abstract: Consider a full-rank weighted least squares problem in which the weight matrix is highly ill-conditioned. Because of the ill-conditioning, standard methods for solving least-squares problems, QR factorization and the nullspace method for example, break down. G.W. Stewart established a norm bound for such a system of equations, indicating that it may be possible to find an algorithm that gives an accurate solution. S.A. Vavasis proposed a new definition of stability that is based on this result. He also defined the NSH algorithm for solving this least-squares problem and showed that it satisfies his definition of stability. In this paper, we propose a complete orthogonal decomposition algorithm to solve this problem and show that it is also stable. This new algorithm is simpler and more efficient than the NSH method.

title: Enhancement of Environments for Analysis of Trace Files of Parallel Programs
abstract: One of the important phases of parallel programming is performance analysis. Trace data provides information about where time is spent in programs. Since this data is huge, a tool for analyzing and visualizing the trace data is convenient and necessary for performance analysis of parallel programs. Environments which provide such a faclility are many and varied. In this report, we discuss our work on the enhancement

of one such environment for accessibility over more platforms and better visualization capabilities. The environment is Pablo.

title: A New Trust Region Algorithm for Equality Constrained Optimization
abstract: We present a new trust algorithm for solving nonlinear equality constrained optimization problems. At each iterate a change of variables is performed to improve the ability of the algorithm to follow the constraint level sets. The algorithm employs L2 penalty function for obtaining global convergence. Under certain assumptions we prove that this algorithm globally converges to a point satisfying the second order necessary optimally conditions; the local convergence rate is quadratic. Results of preliminary numerical experiments are presented.

title: A Quasi-Newton L2-Penalty Method for Minimization Subject to Nonlinear Constraints
abstract: We present a modified L2 penalty function method for equality constrained optimization problems. The pivotal feature of our algorithm is that at every iterate we invoke a special change of variables to improve the ability of the algorithm to follow the constraint level sets. This change of variables gives rise to a suitable block diagonal approximation to the Hessian which is then used to construct a quasi-Newton method. We show that the complete algorithm is globally convergent with a local Q-superlinearly convergence rate. Preliminary results are given for a few problems.

title: Mass-Extinction: Evolution and the Effects of External Influences on Unfit Species
abstract: We present a new model for extinction in which species evolve in bursts or 'avalanches,' during which they become on average more susceptible to environmental stresses such as harsh climates and so are more easily rendered extinct. Results of simulations and analytic calculations using our model show a power-law distribution of extinction sizes which is in reasonable agreement with fossil data. We also see a number of features qualitatively similar to those seen in the fossil record. For example, we seefrequent smaller extinctions in the wake of a large mass extinction, which arise because there is reduced competition for resources in the aftermath of a large extinction event, so that species which would not normally be able to compete can get a foothold, but only until the next cold winter or bad attack of the flu comes along to wipe them out.

title: Eigenmodes of Isospectral Drums
abstract: Recently it was proved that there exist nonisomeric planar regions that have identical Laplace spectra. That is, one cannot "hear the shape of a drum." All known examples of such regions are bounded by polygons

with reentrant corners. While the isospectrality can be proven mathematically, analytical techniques are unable to produce eigenvalues themselves. Furthermore, standard numerical methods for computing the eigenvalues, such as adaptive finite elements, are highly inefficient. Physical experiments have been performed to measure the spectra, but the accuracy and flexibility of this method are limited. We describe an algorithm due to Descloux and Tolley that blends finite elements with domain decomposition, and show that, with a modification that doubles its accuracy, this algorithm can be used to compute efficiently the eigenvalues for polygonal regions. We present results accurate to twelve digits for the most famous pair of isospectral drums, as well as results for another pair.

title: A Level-set Approach Inverse Problems Involving Obstacles
abstract: An approach for solving inverse problems involving obstacles is proposed. The approach uses a level-set method which has been shown to be effective in treating problems involving moving boundaries. We develop two computational methods based on this idea. One method results in a nonlinear time-dependent partial differential equation for the level-set function whose evolution minimizes the residual in the data fit. The second method is an optimization that generates a sequence of level-set functions that reduces the residual. The methods are illustrated in two applications: a deconvolution problem, and a diffraction screen reconstruction problem.

title: Parallel Solution of Sparse Linear Least Squares Problems on Distributed-memory Multiprocessors
abstract: This paper studies the solution of large-scale sparse linear least squares problems on distributed-memory multiprocessors. The method of corrected semi-normal equations is considered. New block-oriented parallel algorithms are developed for solving the related sparse triangular systems. The arithmetic and communication complexities of the new algorithms applied to regular grid problems are analyzed. The proposed parallel sparse triangular solution algorithms together with a block-oriented parallel sparse QR factorization algorithm result in a highly efficient block-oriented approach to the parallel solution of sparse linear least squares problems on distributed-memory multiprocessors. Performance of the block-oriented approach is demonstrated empirically through an implementation on an IBM Scalable POWER parallel system SP2. The largest problem solved has over two million rows and more than a quarter million columns. The execution speed for the numerical factorization of this problem achieves over 3.7 gigaflops per second on an IBM SP2 machine with 128 processors.

title: Model Fermion Monte Carlo with Correlated Pairs
abstract: The issues that prevent the development of efficient and stable algorithms for fermion Monte Carlo in continuum systems are reexamined with special reference to the implications of the "plus/minus" symmetry. This is a property of many algorithms that use signed walkers, namely that the dynamics are unchanged when the signs of the walkers are interchanged. Algorithms that obey this symmetry cannot exhibit the

necessary stability. Specifically, estimates of the overlap with any antisymmetric test function cannot be bounded away from zero in the limit of many iterations. Within the framework of a diffusion Monte Carlo treatment of the Schroedinger equation, it is shown that this symmetry is easily broken for pairs of walkers while at the same time preserving the correct marginal dynamics for each member of the pair. The key is to create different classes of correlations between members of pairs and to use (at least) two distinct correlations for a pair and for the same pair withthe signs exchanged. The ideas are applied successfully for a class of simplemodel problems in two dimensions.

title: Fast Compiled Logic Simulation Using Linear BDDs
abstract: This paper presents a new technique for compiled zero delay logic simulation, and includes extensive experiments that demonstrate its performance on standard benchmarks. Our compiler partitions the circuit into fanout-freeregions (FFRs), transforms each FFR into a linear sized BDD, and converts each BDD into executable code. In our approach, the computation is sublinear in the number of variables within each partition because only one path, from root to leaf, of the BDD is executed; therefore in many cases, substantial computation is avoided. In this way, our approach gets dome to the advantages of oblivious as well as demand-driven evaluation. We investigated the impact of the various heuristics on performance, and based on this data, we recommend good values for design parameters. A performance improvement of up to 67% over oblivious simulation is observed for our benchmarks.

title: Monte Carlo Study of the Random-field Ising Model
abstract: Using a cluster-flipping Monte Carlo algorithm combined with a generalization of the histogram reweighting scheme of Ferrenberg and Swendsen, we have studied the equilibrium properties of the thermal random-field Ising model on a cubic lattice in three dimensions. We have equilibrated systems of L x L x L spins, with values of L up to 32, and for these systems the cluster-flipping method appears to a large extent to overcome the slow equilibration seen in single-spin-flip methods. From the results of our simulations we have extracted values for the critical exponents and the critical temperature and randomnessof the model by finite size scaling. For the exponents we find v=1.02 +- 0.06, B=0.06 +- 0.07, y=1.9 +- 0.2, and mean(y)=2.9 +- 0.2.

title: A Model for Evolution and Extinction
abstract: We present a model for evolution and extinction in large ecosystems. The model incorporates the effects of interactions between species and the influences of abiotic environmental factors. We study the properties of the model by approximate analytic solution and also by numerical simulation, and use it to make predictions about the distribution of extinctions and species lifetimes that we would expect to see in real ecosystems. It should be possible to test these predictions against the fossil record. The model indicates that a possible mechanism for mass extinction is the coincidence of a large coevolutionary avalanche in the ecosystem with a severe environmental disturbance.

title: Multithreaded model for dynamic load balancing parallel adaptive PDE computations
abstract: We present a multithreaded model for the dynamic load-balancing ofnumerical, adaptive computations required for the solution of Partial Differential Equations (PDEs) on multiprocessors. Multithreading is used as a means of exploring concurrency in the processor level inorder to tolerate synchronization costs inherent to traditional (non-threaded) parallel adaptive PDE solvers. Our preliminary analysis for parallel, adaptive PDE solvers indicates that multithreading can be used as a mechanism to mask overheads required for the dynamic balancing of processor workloads with computations required for the actual numerical solution of the PDEs. Also, multithreading can simplify the implementation of dynamic load-balancing algorithms, a task that is very difficult for traditional data parallel adaptive PDE computations. Unfortunately, multithreading does not always simplify program complexity, often makes code re-usability not an easy task, and increases software complexity.

title: An Aspect Ratio Bound for Triangulating a d-grid Cut by a Hyperplane
abstract: We consider the problem of triangulating a d-dimensional uniform grid of d-cubes that is cut by a k-dimensional affine subspace. The goal is to obtain a triangulation with bounded aspect ratio. To achieve this goal, we allow some of the box faces near the affine subspace to be displaced. This problem has applications to finite element mesh generation. For general d and k, the bound on aspect ratio that we attain is double-exponential in d. For the important special case of d = 3, the aspect ratio bound is small enough that the technique is useful in practice.

title: A Newton Acceleration of the Weiszfeld Algorithm for Minimizing the Sum of Euclidean Distances
abstract: The Weiszfeld algorithm for continuous location problems can be considered as an iteratively reweighted least squares method. It exhibits linear convergence. In this paper, a Newton type algorithm with similar simplicity is proposed to solve a continuous multifacility location problem with Euclidean distance measure. Similar to the Weiszfeld algorithm, at each iteration the main computation can be solving a weighted least squares problem. A Cholesky factorization of a symmetric positive definite band matrix, typically with a relatively small band width (e.g., a band width of two for a Euclidean location problem on a plane) is required. This new algorithm can be regarded as a Newton acceleration to the Weiszfeld algorithm with fast global and local convergence. The simplicity and efficiency of the proposed algorithm makes it particularly suitable for large-scale Euclidean location problems and parallel implementation. Computational experience also suggests that the proposed algorithm performs remarkably well in the presence of degeneracy and near degeneracy. In addition, it is proven to be globally convergent. Although the local convergence analysis is still under investigation, computation results suggest that it is typically superlinearly convergent.

title: Pseudospectra of Linear Operators
abstract: The following contains mathematical formulae and symbols that may become distorted in ASCII text format. The advent of ever more powerful computers has brought with it a new way of conceiving some of the fundamental eigenvalue problems of applied mathematics. If a matrix or linear operator "A" is far from normal, its eigenvalues or more generally its spectrum may have little to do with its behavor as measured by quantities such as ||A**N|| or ||exp(tA)||. More may be learned by examining the sets in the complex plane known as the "pseudospectra" of A, defined by level curves of the norm of the resolvent, ||(zI - A)**-1||. Five years ago, the author published a paper that presented computed pseudospectra of thirteen highly non-normal matrices arising in various applications. Since that time, analogous computations have been carried out for differential and integral operators. This paper, a companion to the earlier one, presents ten examples, each chosen to illustrate one or more mathematical or physical principles.

title: Dealing with Dense Rows in the Solution of Sparse Linear Least Squares Problems
abstract: Sparse linear least squares problems containing a few relatively dense rows occur frequently in practice. Straightforward solution of these problems could cause catastrophic fill and delivers extremely poor performance. This paper studies a scheme for solving such problems efficiently by handling dense rows and sparse rows separately. How a sparse matrix is partitioned into dense rows and sparse rows determines the efficiency of the overall solution process. A new algorithm is proposed to find a partition of a sparse matrix which leads to satisfactory or even optimal performance. Extensive numerical experiments are performed to demonstrate the effectiveness of the proposed scheme. A MATLAB implementation is included.

title: Locality-Conscious Load Balancing: Connectionist Architectural Support
abstract: Traditionally, in distributed memory architectures, locality maintenance and load balancing are seen as user level activities involving compiler and runtime system support in software. Such software solutions require an explicit phase of execution, requiring the application to suspend its activities. This paper presents the first (to our knowledge) architecture-level scheme for extracting locality concurrent with the application execution. An artificial neural network coprocessor is used for dynamically monitoring processor reference streams to learn temporally emergent utilities of data elements in ongoing local computations. This facilitates use of kernel-level load balancing schemes thus, easing the user programming burden. The kernel-level scheme migrates data to processor memories evincing higher utilities during load-balancing. The performance of an execution-driven simulation evaluating the proposed coprocessor is presented for three applications. The applications chosen represent the range of load and locality fluxes encounted in parallel programs, with (a) static locality and load characteristics, (b) slowly varying localities for fixed datasetsizes and (c) rapidly fluctuating localities among slowly varying datasetsizes. The performance results indicate the viability and success of the coprocessor in concurrently extracting locality for use in load balancing activities.

title: Multiconfiguration Wavefunctions for Quantum Monte Carlo Calculations of First-row Diatomic Molecules
abstract: We use the variance minimization method to determine accurate wavefunctions for first-row homonuclear diatomic molecules. The form of the wave function is a product of a sum of determinants and a generalized Jastrow factor. One of the important features of the calculation is that we are including low-lying determinants corresponding to single and double excitations from the Hartree-Fock configuration within the space of orbitals whose atomic principal quantum numbers do not exceed those occurring in the Hartree-Fock configuration. The idea is that near-degeneracy correlation is most effectively described by a linear combination of low-lying determinants whereas dynamic correlation is well described by the generalized Jastrow factor. All the parameters occurring in both the determinantal and the Jastrow parts of the wave function are optimized. The optimized wave functions recover 77-94% of the correlation energy

in variational Monte Carlo and 91-99% of the correlation energy in diffusion Monte Carlo.

title: Numerical Conformal Mapping Using Cross-ratios and Delaunay Triangulation
abstract: We propose a new algorithm for computing the Riemann mapping of the unit disk to a polygon, also known as the Schwarz-Christoffel transformation. The new algorithm, CRDT, is based on cross-ratios of the prevertices, and also on cross-ratios of quadrilaterals in a Delaunay triangulation of the polygon. The CRDT algorithm produces an accurate representation of the Riemann mapping even in the presence of arbitrary long, thin regions in the polygon, unlike any previous conformal mapping algorithm. We believe that CRDT can never fail to converge to the correct Riemann mapping, but the correctness and convergence proof depend on conjectures that we have so far not been able to prove. We demonstrate convergence with computational experiments. The Riemann mapping has applications to problems in two-dimensional potential theory and to finite-difference mesh generation. We use CRDT to produce a mapping and solve a boundary value problem on long, thin regions for which no other algorithm can solve these problems.

title: Analysis of the Early Workload on the Cornell Theory Center IBM SP2
abstract: Parallel computers have matured to the point where they are capable of running a significant production workload. Characterizing this workload, however, is far more complicated than for the single-processor case. Besides the varying number of processors that may be invoked, the nodes themselves may provide differing computational resources (memory size, for example). In addition, the batch schedulers may introduce further categories of service which must be considered in the analysis. The Cornell Theory Center (CTC) put a 512-node IBM SP2 system into production in early 1995. Extended traces of batch jobs began to be collected in mid-1995 when the usage base became sufficiently large. This paper offers an analysis of this early batch workload.

title: Structure and Efficient Jacobian Calculation
abstract: Many computational tasks require the determination of the Jacobian matrix, at a given argument, for a large nonlinear system of equations. Calculation or approximation of a Newton step is a related task. The development of robust automatic differentiation (AD) software allows for "painless" and accurate calculation of these quantities; however, straight forward application of AD software on large-scale problems can require an inordinate amount of computation. Fortunately, large-scale systems of nonlinear equations typically exhibit either sparsity or structure in their Jacobian matrices. In this paper we proffer general approaches for exploiting sparsity and structure to yield efficient ways to determine Jacobian matrices (and Newton steps) via automatic differentiation.

abstract: MATLAB(R), a commercial product of The MathWorks, Inc., has become one of the principal languages of desktop scientific computing. A system is described that enables one to run MATLAB conveniently on multiple processors. Using short, MATLAB-style commands like Eval, Send, Recv, Bcast, Min, and Sum, the user operating within one MATLAB session can start various processes in a fashion that maintains MATLAB's traditional user-friendliness. Multi-processor graphics is also supported. The system currently runs under MPICH on an IBM SP2 or a network of Unix workstations, and extensions are planned to networks of PCs. MultiMATLAB is potentially useful for education in parallel programming, for prototyping parallel algorithms, and for fast and convenient execution of easily parallelizable numerical computations on multiple processors.

title: The Chebyshev Polynomials of a Matrix
abstract: A Chebyshev polynomial of a square matrix A is a monic polynomial of specified degree that minimizes ||p(A)||(sub2). The study of such polynomials is motivated by the analysis of Krylov subspace iterations in numerical linear algebra. An algorithm is presented for computing these polynomials based on reduction to a semidefinite program which is then solved by a primal-dual interior point method. Examples of Chebyshev polynomials of matrices are presented, and it is noted that if A is far from normal, the lemniscates

of these polynomials tend to approximate pseudospectra of A.

title: Domain Decomposition Methods for Conformal Mapping and Eigenvalue Problems
abstract: Domain decomposition is widely used in the numerical solution of elliptic boundary value problems. It is appealing in part because of improved efficiency and straightforward parallelization. Conceptually, domain decomposition often exploits a natural feature of elliptic problems: data at one point may have an exceedingly weak influence on the solution at a far-removed point. The application of domain decomposition to other elliptic problems is less fully developed. One such area is numerical conformal mapping. We introduce the SC Toolbox for Matlab, an interactive graphical software package for the Schwarz-Christoffel mapping of polygons. The Toolbox can be used for interior and exterior mapping from several fundamental domains. Elongations in the polygon lead to crowding, in which the preimages of affected vertices are exponentially close together. Such regions are candidates for decomposition. We describe CRDT, an overlapping subdomain method developed with Vavasis for numerical Schwarz-Christoffel mapping. The method uses Delaunay triangulation to decompose the polygon into overlapping quadrilaterals, which in turn define cross-ratios that form the basis of a nonlinear system. Each quadrilateral induces an embedding of the prevertices so that locally, the map can be computed accurately. Apparently CRDT can deal with any degree of crowding, as is demonstrated by examples. Another application in conformal mapping is in Symm's integral equation. An important feature of existing software for Symm's equation is the efficient treatment of corner singularities. Careful generalization to multiple domains allows this treatment to be preserved and extended. An onoverlapping formulation leads to a linear system that is ideal for Schur complementation. The resulting method asymptotically requires a fraction of the single-domain work and is easily parallelized. We also consider a domain decomposition algorithm for the Laplace eigenvalue problem on polygons. This method, an improvement on one described by Descloux and Tolley, searches for the matching of Fourier-Bessel expansions at each corner to locate eigenvalues. We apply the algorithm to the "isospectral drums" discovered by Gordon, Webb, and Wolpert to find 25 eigenvalues to 12 digits. The method is far more accurate and efficient than standard methods for this problem.

title: Toward a Portable Parallel Library for Space-Time Adaptive Methods
abstract: Space-time adaptive processing (STAP) refers to a class of methods for detecting targets using an array of sensors. The output of the array is weighted using data collected from the sensors over a given period of time. An optimal method of calculating weights exists; however, this method is usually computationally impractical. Therefore, various heuristic methods are used that approximate the optimal method. These heuristics use many of the same operations and are computationally demanding. We are in the process of constructing a portable, parallel library of subroutines useful for constructing STAP heuristics. As a first step in this process, we implemented one STAP heuristic, higher-order post-Doppler processing, using three different parallel methods on the IBM SP2 and the Intel Paragon: these methods characterize different parallel approaches to the STAP problem. From implementing these algorithms, we have been able to identify components for our parallel library. We propose models for some of the components and give preliminary timing results for the parallel methods.

title: Workload Evolution on the Cornell Theory Center IBM SP2
abstract: The Cornell Theory Center (CTC) put a 512-node IBM SP2 system into production in early 1995, and extended traces of batch jobs began to be collected in June of that year. An analysis of the workload shows that it has not only grown, but that its characteristics have changed over time. In particular, job duration increased with time, indicative of an expanding production workload. In addition, there was increasing use of parallelism. As the load has increased and larger jobs have become more frequent, the batch management software (IBM's LoadLeveler) has had difficulty in scheduling the requested resources. New policies were established to improve the situation. This paper will profile how the workload has changed over time and give anin-depth look at the maturing workload. It will examine how frequently certain resources are requested and analyze user submittal patterns. It will also describe the policies that were implemented to improve the scheduling situation and their effect on the workload.

title: Matrix Iterations: The Six Gaps Between Potential Theory and Convergence
abstract: The theory of the convergence of Krylov subspace iterations for linear systems of equations (conjugate gradients, biconjugate gradients, GMRES, QMR, Bi-CGSTAB, ...) is reviewed. For a computation of this kind, an estimated asymptotic convergence factor rho less than 1 can be derived by solving a problem of potential theory or conformal mapping. Six approximations are involved in reducing the actual computation to this scalar estimate. These six approximations are discussed in a systematic way and illustrated by a sequence of examples computed with tools of numerical conformal mapping and semidefinite programming.

title: Self-organized criticality, evolution, and extinction
abstract: Statistical analysis indicates that the fossil exctinction record is compatible with a distribution of extinction events whose frequency is related to their size by a power law with exponent tau approx. = 2. This result is in agreement with preductions based on self-organized critical models of extinction, and might well be taken as evidence for self-organizing behavior in terrestrial evolution. We argue however that there is a much simpler explanation for the appearance of a power law in terms of extinctions caused by stresses (either biotic or abiotic) to which species are subjected by their environment. We give an explicit model of this process and discussits properties and implications for the interpretation of the fossil record.

title: Separation of the Exchange-Correlation Potential into Exchange plus Correlation: an Optimized Effective Potential Approach
abstract: Most approximate exchange-correlation functionals used within density functional theory are

constructed as the sum of two distinct contributions for exchange and correlation. Separating the exchange component from the entire functional is useful since, for exchange, exact relations exist under uniform density scaling and spin scaling. In the past, accurate exchange-correlation potentials have been generated from essentially exact densities but they have not been correctly decomposed into their separate exchange and correlation components (except for two-electron systems). Using a recently proposed method, equivalent to the solution of an optimized effective potential problem with the corresponding orbitals replaced by the exact Kohn-Sham orbitals, we obtain the separation according to the density functional theory definition. We compare the results for the Ne and Be atoms with those obtained by the previously used appromixate separation scheme.

title: Generalized gradient approximations to density functional theory: comparison with exact results
abstract: In order to assess the accuracy of commonly used approximate exchange-correlation density functionals, we present a comparison of accurate exchange and correlation potentials, exchange energy densities and energy components with the corresponding approximate quantities. Four systems are used as illustrative examples: the model system of two electrons in a harmonic potential and the De, Be and Ne atoms. A new ingredient in the paper is the separation of the exchange-correlation potential into exchange and correlation according to the density functional theory definition.

title: On the Efficient Methods to Solve ODEs and BVPs Using Automatic Differentiation
abstract: A large number of physical phenomena are modeled by a system of ODEs or a system of implicit ODEs. We demonstrate applicability of automatic differentiation (AD) for solving: (1) Boundary value problems in ODEs and implicit ODEs. (2) Initial state and parameter estimation problems. The impact of using AD is two fold. Firstly, efficient methods for computing the gradient vectors and Jacobian matrices have been developed using AD. Secondly the process of getting derivatives via AD is robust, more user friendly, and provides error free derivatives. Furthermore, techniques using AD have been developed which exploit structure in the user's computation, and particularly the structure we observe in boundary value problems or state/parameter estimation problems. We demonstrate by a few experiments the efficiency gained by the usage of AD in solving these problems.

title: Stable and Efficient Solution of Weighted Least-Squares Problems with Applications in Interior Point Methods
abstract: In this thesis, we consider two closely related problems. The first is a full-rank weighted least-squares problem with a weight matrix that is positive definite, diagonal, and extremely ill conditioned. The ill-conditioning can cause standard algorithms to compute solutions with, in some cases, no digits of accuracy. Theory suggests the existence of an algorithm that will compute an accurate solution despite the ill-conditioning in the weight matrix. We describe a new algorithm, the Complete Orthogonal Decomposition (COD) Algorithm, for solving the weighted least-squares problem and show that it has this desirable property. In addition, the COD Algorithm is based on standard, well-understood techniques and is straightforward to implement. A natural application for the weighted least-squares problem described in the previous paragraph is interior point methods for linear programming. We discuss the problem in this context, and describe how the COD algorithm can be extended and used in this setting. Unlike other algorithms, this one is stable for interior point methods without assuming nondegeneracy in the linear programming instance. Computational experiments indicate that it is more reliable than other algorithms when the problem is near degenerate. The second problem involves a particular interior point algorithm. In 1994, Vavasis and Ye proposed a new primal-dual path-following interior point method, the layered-step interior point (LIP) method. This algorithm interleaves traditional steps with longer, layered least-squares (LLS) steps. Computation of a LLS step requires solving a weighted least-squares problem similar to the one described above, but the weight matrix also has the property that the weights fall into well-separated groups. This additional structure allows the problem to be broken down into smaller, constrained problems with well-conditioned weight matrices. The smaller problems can then be solved stably with standard algorithms, and the LLS step can be computed. Vavasis and Ye did not propose a particular algorithm for solving the LLS problem. In this thesis, we present an algorithm based on Cholesky factorization. The algorithm is such that a modified version of the sparse Cholesky code of Ng and Peyton of Oak Ridge National Laboratories can be used. Thus, the theoretical results are straight forward, and this algorithm proves to be accurate and efficient in practice.

title: Structure and Efficient Hessian Calculation
abstract: Modern methods for numerical optimization calculate (or approximate) the matrix of second derivatives, the Hessian matrix, at each iteration. The recent arrival of robust software for automatic differentiation allows for the possibility of automatically computing the Hessian matrix, and the gradient, given a code to evaluate the objective function itself. However, for large-scale problems direct application of automatic differentiation may be unacceptably expensive. Recent work has shown that this cost can be dramatically reduced in the presence of sparsity. In this paper we show that for structured problems it is possible to apply automatic differentiation tools in an economical way - even in the absence of sparsity in the Hessian.

title: Non-normal Dynamics and Hydrodynamic Stability

abstract: This thesis explores the interaction of non-normality and nonlinearity incontinuous dynamical systems. A solution beginning near a linearly stable fixed point may grow large by a linear mechanism, if the linearization is non-normal, until it is swept away by nonlinearities resulting in a much smaller basin of attraction than could possibly be predicted by the spectrum of the linearization. Exactly this situation occurs in certain linearly stable shear flows, where the linearization about the laminar flow may be highly non-normal leading to the transient growth of certain small disturbances by factors which scale with the Reynolds number. These issues are brought into focus in Chapter 1 through the study of atwo-dimensional model system of ordinary differential equations proposed by Trefethen, et al. [Science, 261, 1993]. In Chapter 2, two theorems are proved which show that the basin of attraction of a stable fixed point, in systems of differential equations combining a non-normal linear term with quadratic nonlinearities, can decrease rapidly as the degree of non-normality is increased, often faster than inverse linearly.
Several different low-dimensional models of transition to turbulence are examined in Chapter 3. These models were proposed by more than a dozen authors for a wide variety of reasons, but they all incorporate non-normal linear terms and quadratic nonlinearities. Surprisingly, in most cases, the basin of attraction of the "laminar flow" shrinks much faster than the inverse Reynolds number.
Transition to turbulence from optimally growing linear disturbances, streamwise vortices, is investigated in plane Poiseuille and plane Couette flows in Chapter4. An explanation is given for why smaller streamwise vortices can lead to turbulence in plane Poiseuille flow. In plane Poiseuille flow, the transient linear growth of streamwise streaks caused by non-normality leads directly to a secondary instability. Certain unbounded operators are so non-normal that the evolution of infinitesimal perturbations to the fixed point is entirely unrelated to the spectrum, even as i to infinity. Two examples of this phenomenonare presented in Chapter 5.

title: Optimal Portfolio Selection with Fixed Transactions Costs in the presence of Jumps and Random Drift
abstract: In this paper, we study the general problem of optimal portfolio selection with fixed transactions costs in the presence of jumps. We extend the analysis of Morton and Pliska to this setting by modeling the return processes of the risky assets in the investor's portfolio as jump-diffusion processes and derive the expression for the related optimal stopping time problem of a Markov process with jumps and explicitly solve it in the situation when the portfolio consists only of one risky asset. We also provide an asymptotic analysis of our model with one risky asset following the ideas of Wilmott and Atkinson. In the process, we also obtain a solution for the "Merton problem" generalized to the situation when there is credit risk. Finally, we consider the case where the drift of the stockprice process is random and unobservable and obtain expressions for the optimal trading policies.

title: A critical assessment of the Self-Interaction Corrected Local Density Functional method and its algorithmic implementation
abstract: We calculate the electronic structure of several atoms and small molecules by direct minimization of the Self-Interaction Corrected Local Density Approximation (SIC-LDA) functional. To do this we first derive an expression for the gradient of this functional under the constraint that the orbitals be orthogonal and show that previously given expressions do not correctly incorporate this constraint. In our atomic calculations the SIC-LDA yields total energies, ionization energies and charge densities that are superior to results obtained with the Local Density Approximation (LDA). However, for molecules SIC-LDA gives bond lengths and reaction energies that are inferior to those obtained from LDA. The nonlocal BLYP functional, which we include as a representative GGA functional, out performs both LDA and SIC-LDA forall ground state properties we considered.

title: Symmetry, Nonlinear Bifurcation Analysis, and Parallel Computation
abstract: In the natural and engineering sciences the equations which model physical systems with symmetry often exhibit an invariance with respect to a particular group "G" of linear transformations. "G" is typically a linear representation of a symmetry group "g" which characterizes the symmetry of the physical system. In this work, we will discuss the natural parallelism which arises while seeking families of solutions to a specific class of nonlinear vector equations which display a special type of group invariance, referred to as equivariance. The inherent parallelism stems for a global de-coupling, due to symmetry, of the full nonlinear equations which effectively splits the original problem into a set of smaller problems. Numerical results from asymmetry-adapted numerical procedure, (MMcontcm.m), written in MultiMATLAB are discussed.

title: Accurate Solution of Weighted Least Squares by Iterative Methods
abstract: We consider the weighted least-squares (WLS) problem with a very ill-conditioned weight matrix. Weighted least-squares problems arise in many applications including linear programming, electrical networks, boundary value problems, and structures. Because of roundoff errors, standard iterative methods for solving a WLS problem with ill-conditioned weights may not give the correct answer. Indeed, the difference between the true and computed solution (forward error) may be large. We propose an iterative algorithm, called MINRES-L, for solving WLS problems. The MINRES-L method is the application of MINRES, a Krylov-space method due to Paige and Saunders, to a certain layered linear system. Using a simplified model of the effects of round off error, we prove that MINRES-L gives answers with small forward error. We present computational experiments for some applications.

title: Hedging a Portfolio of derivatives by Modeling Cost
abstract: We consider the problem of hedging the loss of a given portfolio of derivatives using a set of more liquid derivative instruments. We illustrate why the typical mathematical formulation for this hedging problem is ill-posed. We propose to determine a hedging portfolio by minimizing a proportional cost subject to an upper bound on the hedge risk; this bound is typically slightly larger than the optimal hedge risk achievable without cost consideration. We illustrate that the optimal hedging portfolio obtained by the proposed method is attractive since it consists of fewer instruments with a comparable risk. Finally we illustrate the importance of modeling volatility uncertainty in hedge risk minimization.

title: Automated Application-level Checkpointing of MPI Programs
abstract: Because of increasing hardware and software complexity, the running time of many computational science applications is now more than the mean-time-to-failure of high-performance computing platforms. Therefore, computational science applications need to tolerate hardware failures. In this paper, we focus on the stopping failure model in which a faulty process hangs and stops responding to the rest of the system. We argue that tolerating such faults is best done by an approach called application-level coordinated non-blocking

checkpointing, and that existing fault-tolerance protocols in teh literature are not suitable for implementing this approach. In this paper, we present a suitable protocol, and show how it can be used with a precompiler that instruments C/MPI programs to save application and MPI library state. An advantage of our approach is that it is independent of the MPI implementation. We present experimental results that argue that the overhead of using our system can be small.

title: Semi-supervised Clustering with User Feedback
abstract: We present a new approach to clustering based on the observation that ``it is easier to criticize than to construct.'' Our approach of {\em semi-supervised clustering} allows a user to iteratively provide feedback to a clustering algorithm. The feedback is incorporated in the form of constraints which the clustering algorithm attempts to satisfy on future iterations. These constraints allow the user to guide the clusterer towards clusterings of the data that the user finds more useful. We demonstrate semi-supervised clustering with a system that learns to cluster news stories from a Reuters data set. %This paper presents semi-supervised clustering, a new approach to %clustering that allows users to provide advice to the clustering %algorithm that guides it towards clusterings they prefer. %Semi-supervised clustering begins with traditional, fully unsupervised %clustering to find an initial clustering of the data. The clustered %data is then presented to the user so that they may critique it. User %feedback provides a set of constraints that the system tries to %satisfy to find a new clustering that the user prefers. This process %of presenting clustered data to the user, and refining the clustering %in response to user feedback, is repeated until the user is happy with %the clusters. We present a clustering algorithm that learns from user %feedback to find a clustering metric that yields clusters the user is %happy with. We demonstrate the algorithm on the Reuters and 20 %Newsgroups domains.

title: A Logic of Events
abstract: There is a well-established theory and practice for creating correct-by-construction functional programs by extracting them from constructive proofs of assertions of the form "For all x:A there exists y:B.R(x,y))." There have been several efforts to extend this methodology to concurrent programs, say by using linear logic, but there is no practice and the results are limited. In this paper we define a logic of events that justifies the extraction of correct distributed processes from constructive proofs that system specifications are achievable, and we describe an implementation of an extraction process in the context of constructive type theory. We show that a class of message automata, similar to IO automata and to active objects, are realizers for this logic. We provide a relative consistency result for the logic. We show an example of protocol derivation in this logic, and show how to embed temporal logics such as TLA+ in the event logic.

title: Parametrized Tractability of Edge-Disjoint Paths on Directed Acyclic Graphs

abstract: Given a graph and pairs $s_i t_i$ of terminals, the edge-disjoint paths problem is to determine whether there exist $s_i t_i$ paths that do not share any edges. We consider this problem on ditected acyclic graphs. It is known to be NP-complete and solvable in time $n^{O(k)}$ where k is the number of paths. It has been a long-standing open question whether it is fixed-parameter tractable in k. We resolve this question in the negative: we show that the problem is $W[1]$-hard. In fact it remains $W[1]$-hard even if the demand graph consists of two sets of parallel edges. On a positive side, we give an $O(k! n)$ algorithm for the special case when G is acyclic and $G+H$ is Eulerian, where H is the demand graph. We generalize this result (1) to the case when $G+H$ is ``nearly" Eulerian, (2) to an analogous special case of the unsplittable flow problem. Finally, we consider a related NP-complete routing problem when only the first edge of each path cannot be shared, and prove that it is fixed-parameter tractable on directed graphs.

title: Quantified Constraint Satisfaction Problems: Closure Properties,
Complexity, and Proof Systems
abstract: There has been much prior work on understanding the complexity of the constraint satisfaction problem (CSP), a broad framework capturing many combinatorial problems. This paper studies a natural and strict generalization of the CSP, the quantified constraint satisfaction problem (QCSP). In the CSP, all variables are existentially quantified; in the QCSP, some variables may be universally quantified. Our contributions include proof systems for the QCSP and the identification of three broad tractable subclasses of the QCSP. Central to our study is the algebraic notion of closure properties of constraints, which has been previously used to study the CSP.

title: A Linearly Typed Assembly Language
abstract: Today's type-safe low-level languages rely on garbage collection to recycle heap-allocated objects safely. We present LTAL, a safe, low-level, yet simple language that ``stands on its own": it guarantees safe execution within a fixed memory space, without relying on external run-time support. We demonstrate the expressiveness of LTAL by giving a type-preserving compiler for the functional core of ML. But this independence comes at a steep price: LTAL's type system imposes a draconian discipline of linearity that ensures that memory can be reused safely, but prohibits any useful kind of sharing. We present the results of experiments with a prototype LTAL system that show just how high the price of linearity can be.

title: First-Class Phantom Types
abstract: Classical phantom types are datatypes in which type constraints are expressed using type variables that do not appear in the datatype cases themselves. They can be used to embed typed languages into Haskell or ML. However, while such encodings guarantee that only well-formed data can be constructed, they do not permit type-safe deconstruction without additional tagging and run-time checks. We introduce first-class phantom types, which make such constraints explicit via type equations. Examples of first-class phantom types include typed type representations and typed higher-order abstract syntax trees. These types can be used to support typed generic functions, dynamic typing, and staged compilation in higher-order, statically typed languages such as Haskell or Standard ML. In our system, type constraints can be equations between type constructors as well as type functions of higher-order kinds. We prove type soundness and decidability for a Haskell-like language extended by first-class phantom types.

title: Quantified Constraint Satisfaction and Small Commutative Conservative Operations
abstract: The constraint satisfaction problem (CSP) is a broad framework capturing many combinatorial search problems. A natural and strict generalization of the CSP is the quantified constraint satisfaction problem (QCSP). The CSP involves deciding the truth of constraint networks where all variables are existentially quantified; the QCSP is defined similarly, but variables may be both existentially and universally quantified. While the CSP and QCSP are in their general formulation intractable, they can be parameterized by restricting the constraint language, that is, the types of constraints that are permitted in problem instances. Much attention has been directed towards classifying the complexity of all constraint languages in the case of the CSP. In this paper, we continue the recently initiated study of QCSP complexity by identifying a new family of tractable constraint languages, namely, constraint languages over domains of small size that are closed under a commutative conservative operation. This gives the first QCSP tractability result based on binary operations which may be non-associative. We also give a complete classification of maximal constraint languages over domains of size three.

title: An Optimizing Compiler for Batches of Temporal Logic Formulas
abstract: Model checking based on validating temporal logic formulas has proven practical and effective for numerous applications from verifying hardware designs to proving the correctness of software. As systems based on this approach have become more mainstream, a need has arisen to deal effectively with large batches of formulas over a common model. Presently, most systems validate formulas one at a time, with little or no interaction between validation of separate formulas. This is the case despite the fact that for a wide range of applications a certain level of redundancy between domain-related formulas can be anticipated. This paper presents an optimizing compiler for batches of temporal logic formulas. A component of the Carnauba Model Checking System, this compiler addresses the need to handle batches of temporal logic formulas by leveraging the framework common to optimizing programming language compilers. Just as a traditional optimizing compiler attempts to exploit redundancy and other solvable properties in programs to reduce the demand on a runtime system, this compiler exploits similar properties in groups of formulas to reduce the demand on a model checking engine. Optimizations are performed via a set of distinct, interchangeable

optimization passes operating on a common intermediate representation. The intermediate representation is capable of representing formulas over the full modal mu-calculus, and the optimization techniques are applicable to any temporal logic that can be translated into the modal mu-calculus. The compiler offers a unified framework for expressing well understood single-formula optimizations as well as numerous inter-formula optimizations that capitalize on redundancy and logical implication. The result is a system that, when applied to a potentially heterogeneous collection of formulas over a common problem domain, is able to measurably reduce the time and space requirements of the subsequent model checking engine.

title: TeXQuery: A Full-Text Search Extension to XQuery
abstract: One of the key benefits of XML is its ability to represent a mix of structured and unstructured (text) data. Although current XML query languages such as XPath and XQuery can express rich queries over structured data, they can only express very rudimentary queries over text data. We thus propose TeXQuery, which is a powerful full-text search extension to XQuery. TeXQuery provides a rich set of fully composable full-text search primitives, such as Boolean connectives, phrase matching, proximity distance, stemming and thesauri. TeXQuery also enables users to seamlessly query over both structured and text data by embedding TeXQuery primitives in XQuery, and vice versa. Finally, TeXQuery supports a flexible scoring construct that can be used to score query results based on full-text predicates. TeX- Query is one of the proposals submitted to the W3C Full-Text Task Force, whose charter is to extend XQuery with full-text search capabilities.

title: Resolving Constrained Existential Queries over Context-Sensitive Analyses
abstract: A context-sensitive analysis is an analysis in which program elements are interpreted with respect to the context in which they occur. For analyses on imperative languages, this often refers to considering the behavior of called procedures with respect to the calling-stack contexts that precede them. Algorithms for performing or approximating these types of analyses make up the core of interprocedural program analysis and are pervasive; having applications in program optimization, checkpointing, and model checking. This paper presents an abstraction of a popular form of context-sensitive analysis based on iteratively encapsulating the cumulative effect of a recurring piece of code. Given an analysis fitting this abstraction, a technique is presented for resolving queries of the form: Is there an occurring context, subject to a given stack-context constraint, in which a particular set of facts holds at a particular location? This practical technique, based on manipulating regular languages, is capable not only of answering queries of this form, but also of generating a compact mechanism for dynamically applying the output of the analysis to contexts as they occur. A comprehensive example is presented along with performance data on a case study code. Finally, a selection of potential applications is discussed.

title: Region Analysis for Imperative Languages
abstract: This paper presents a region inference framework designed specifically for imperative programs with dynamic allocation and destructive updates. Given an input program, the algorithm automatically translates it into an output program with region annotations on procedures and allocation commands, and with explicit region creation and removal commands. Our framework formulates the analysis problem as a three-step algorithm. In the first phase, it infers region annotations for record declarations in the input language. Second, it performs a unification-based flow analysis of the program, inferring region types at each point in the program. In particular, it determines region types for allocation commands and procedure calls. In the third phase, it uses a single-pass algorithm to inspect each point in the program and insert region creation and removal commands in the control flow of the output program. This transformation ensures that regions are live whenever they are being used, while minimizing region lifetimes. The algorithm is simple, efficient, and provably correct. Furthermore, we show that the framework can be extended with more aggressive analyses (at the expense of making it less modular or more complex), such as interprocedural region liveness or shape analysis, to further improve the accuracy and performance of memory management. More generally, our framework allows existing analysis technology for imperative languages, such as points-to or shape analysis, to be easily integrated and applied to the region inference problem.

title: The Inlined Reference Monitor Approach to Security Policy Enforcement
abstract: Embedding security enforcement code into applications is an alternative to traditional security mechanisms. This dissertation supports the thesis that such Inlined Reference Monitors, or IRMs, offer many advantages and are a practical option in modern systems. IRMs enable flexible general-purpose enforcement of security policies, and they are especially well suited for extensible systems and other non-traditional platforms. IRMs can exhibit similar, or even better, performance than previous approaches and can help increase assurance by contributing little to the size of a trusted computing base. Moreover, IRMs' agility in distributed settings allows for their cost-effective and trustworthy deployment in many scenarios. In this dissertation, IRM implementations are derived from formal automata-based specifications of security policies. Then, an IRM toolkit for Java is described in detail. This Java IRM toolkit uses an imperative policy language that allows a security policy, in combination with the details of its enforcement, to be given in a single complete specification. Various example policies, including the stack-inspection policy of Java, illustrate the approach. These examples shed light on practical issues in policy specification, the support needed from an IRM toolkit, and the advantages of the IRM approach.

title: On the Completeness of Full-Text Search Languages for XML
abstract: We study formal properties of full-text search languages for XML. Our main contribution is the development of a formal model for full-text search based on the positions of tokens in XML nodes. Building on this model, we define a full-text calculus based on first-order logic, and a full-text algebra based on the relational algebra. We show that the full-text calculus and algebra are equivalent even in the presence of arbitrary position-based predicates, such as distance predicates and phrase matching. This suggests a notion of completeness for full-text languages. None of the full-text search languages that we are aware of are complete under the above characterization. We propose a new full-text language that is complete and naturally generalizes existing full-text languages. Our formalization in terms of the relational model can also serve as the basis for (a) joint optimization of structured and full-text search queries, and (b) ranking full-text search query results by leveraging existing work on the probabilistic relational model.

title: Machine Learning for Coreference Resolution: Recent Successes and
Future Challenges
abstract: State-of-the-art coreference resolution systems are mostly knowledge-based systems that operate by relying on a set of hand-crafted coreference resolution heuristics. Recently, however, machine learning approaches have been shown to be a promising way to build coreference resolution systems that are more robust than their knowledge-based counterparts. Nevertheless, there are several key issues in existing machine learning approaches to the problem that are either not explored or being overlooked, potentially leading to a deterioration of system performance. This document examines each of these issues in detail and suggests potential solutions.

title: Prediction of protein-protein interactions and the interaction site from sequence information - an extensive study of the co-evolution model
abstract: This paper studies new variants of the co-evolution model for prediction of protein-protein interactions from sequence information. Given two query proteins, the method uses information extracted from a database search to generate a multiple alignment and compute the likelihood that the two proteins interact. The model uses four elements, starting from the correlated divergence between proteins from different species, through potentials of correlated mutations, charge and hydrogen bonds. The significance of these measures is estimated from large populations of interacting and non interacting protein pairs. A variant over an EM algorithm is used to identify the subset of the database proteins (the homologs of the query proteins) that are more likely to interact, and a modified correlated mutations model is employed to maximize the strength of the signals. The algorithm not only tries to suggest if two proteins interact, but also attempts to detect the localized binding box interaction region, information that is hardly ever available. We tune and test our model over a large set of protein interactions we extract from BIND.

title: A comprehensive study of the notion of functional link between genes based on microarray data, promoter signals, protein-protein interactions and pathway analysis
abstract: It is commonly accepted that genes with similar expression profiles are functionally related. However, so far no clear distinction has been made as for the type of the functional link between genes as suggested by microarray data. Similarly expressed genes can be part of the same complex as interacting partners; they can participate in the same pathway without interacting directly; they can perform similar functions; or they can simply have similar regulatory sequences. Here we embark on a rigorous study of the notion of functional link as implied from expression data. We analyze different similarity measures of gene expression profiles and assess their usefulness and robustness in detecting biological relationships by comparing the similarity scores with results obtained from databases of interacting proteins, promoter signals, and cellular pathways, as well as through sequence comparisons and pathway modeling. We also introduce new similarity measures we specifically developed for the analysis of expression data. These measures are based on statistical analysis and better discriminate genes which are functionally nearby and faraway. With the optimized similarity measures we proceed to analyze other aspects of this data.

Specifically, we introduce a method of inferring the type of relationship by correlating the expression data with all the other data sets. This method allows us to not only predict when genes are functionally related but also to suggest how they are related. We then cluster the data using clustering algorithms that are specially tailored to deal with noisy data. Finally we propose methods for assessing the significance of clusters and study the correspondence between gene clusters and biochemical pathways.

title: The URMS-RMS hybrid algorithm for fast and sensitive local protein structure alignment
abstract: We present an efficient and sensitive hybrid algorithm for local structure alignment of a pair of 3D protein structures. The hybrid algorithm employs both the URMS (Unit-vector Root Mean Squared) metric and the RMS metric. Initial transformations (rotations) are identified using the algorithm. These rotations are then clustered and an RMS based dynamic programming algorithm is invoked to find the maximal local similarities for representative rotations of the clusters. Our algorithm searches efficiently the transformation space using a fast screening protocol. Given the transformation based parameters, the algorithm rigorously finds the optimal alignments. Statistical significance of the alignments is estimated using a model that accounts for both the score of the match and the RMS. We tested our algorithm over the SCOP classification of protein domains. Our algorithm performs very well, its main advantages being (1) it combines the RMS and the URMS metrics (2) it searches extensively the transformation space (3) it can detect complex similarities and structural repeats (4) it is symmetric.

title: Type Theoretical Foundations for Data Structures, Classes, and Objects
abstract: In this thesis we explore the question of how to represent programming data structures in a constructive type theory. The basic data structures in programing languages are records and objects. Most known papers treat such data structure as primitive. That is, they add new primitive type constructors and supporting axioms for records and objects. This approach is not satisfactory. First of all it complicates a type theory a lot. Second, the validity of the new axioms is not easily ablished. As we will see the naive choice of axioms can lead to contradiction even in the simplest cases. We will show that records and objects can be defined in a powerful enough type theory. We will also show how to use these type constructors to define abstract data structure.

title: Dynamic Security Labels and Noninterference
abstract: This paper explores information flow control in systems in which the security classes of data can vary dynamically. Information flow policies provide the means to express strong security requirements for data confidentiality and integrity. Recent work on security-typed programming languages has shown that information flow can be analyzed statically, ensuring that programs will respect the restrictions placed on data. However, real computing systems have security policies that vary dynamically and that cannot be determined at the time of program analysis. For example, a file has associated access permissions that

cannot be known with certainty until it is opened. Although one security-typed programming language has include support for dynamic security labels, there has been no examination of whether such a mechanism can securely control information flow. In this paper, we present an expressive language-based mechanism for securely manipulating dynamic security labels. The mechanism is presented both in the context of a Java-like programming language and, more formally, in a core language based on the typed lambda calculus. This core language is expressive enough to encode previous dynamic label mechanisms; as importantly, any well-typed program is provably secure because it satisfies noninterference.

title: Querying Peer-to-Peer Networks Using P-Trees
abstract: Peer-to-peer (P2P) systems provide a robust, scalable and decentralized way to share and publish data. However, most existing P2P systems only provide a very rudimentary query facility; they only support equality or keyword search queries over files. We believe that future P2P applications, such as resource discovery on a grid, will require more complex query functionality. As a first step towards this goal, we propose a new distributed, fault-tolerant P2P index structure for resource discovery applications called the P-tree. P-trees efficiently evaluate range queries in addition to equality queries. We describe algorithms to maintain a P-tree under insertions and deletions of data items/peers, and evaluate its performance using both a simulation and a real distributed implementation. Our results show the efficacy of our approach.

title: Knowledge-Based Sythesis of Distributed Systems Using Event Structures
abstract: To produce a program guaranteed to satisfy a given specification one can synthesize it from a formal constructive proof that a computation satisfying that specification exists. This process is particularly effective if the specifications are written in a high-level language that makes it easy for designers to specify their goals. We consider a high-level specification language that results from adding knowledge to a fragment of Nuprl specifically tailored for specifying distributed protocols, called event theory. We then show how high-level knowledge-based programs can be synthesized from the knowledge-based specifications using a proof development system such as Nuprl. Methods of Halpern and Zuck [1992] then apply to convert these knowledge-based protocols to ordinary protocols. These methods can be expressed as heuristic transformation tactics in Nuprl.

title: Performance Analysis of the Pipe Problem, a Multi-Physics Simulation Based on Web Services
abstract: The ongoing convergence of grid computing and web services has inspired a number of studies on the use of SOAP-based web services for scientific computing. These studies have exposed several performance problems in using SOAP-based communication; to eliminate these bottlenecks, extensions to the SOAP standard and sophisticated implementation strategies have been proposed. In this paper, we will describe the ASP system, a simulation testbed based on web services for simulating multi-physics, coupled fluid/thermal/mechanical/fracture problems. The system is organized as a collection of geographically-distributed software components in which each component provides a web service, and uses standard SOAP-based web service protocols to interact with other components. There are a number of advantages to organizing a system in this way, which we discuss. We have analyzed the performance of our system for several applications and a number of problem sizes and have found that the overhead for using SOAP-based web services is small and tends to decrease as the problem size increases. Our results suggest that the previously identified potential bottlenecks may not be major issues in practice, and that a standards-compliant implementation like ours can delivery excellent scalable performance even on tightly-coupled problems, provided web services are used judiciously.

title: Better than 1 Hop Lookup Performance with Proactive Caching
abstract: High lookup latencies prohibit peer-to-peer overlays from being used in many performance intensive applications, even though they provide self-organization, scalability, and failure resilience. In this paper, we show that lookup performance of structured DHTs can be improved to any desirable constant, even under 1 hop, by controlled proacive replication. By exploiting the popularity distribution of objects, we can minimize the number of replicas and reduce the storage and bandwidth cost of replication. This enables structured DHTs to efficiently support a wide variety of latency sensitive applications. We describe three different applications, namely DNS, web access, and content distribution, and show how they can derive significant performance gains by using DHTs.

title: Semantic Approximation of Data Stream Joins
abstract: We consider the problem of approximating sliding window joins over data streams in a data stream processing system with limited resources. In our model, we deal with resource constraints by shedding load in the form of dropping tuples from the data streams. We make two main contributions. First, we define the problem space by discussing architectural models for data stream join processing and surveying suitable measures for the quality of an approximation of a set-valued query result. Second, we examine in detail a large part of this problem space. More precisely, we consider the number of generated result tuples as the quality measure, and we propose optimal offline and fast online algorithms for it. In a thorough experimental study with synthetic and real data we show the efficacy of our solutions.

title: Expressing and Implementing the Computational Content Implicit in Smullyan's Account of Boolean Valuations
abstract: In Smullyan's classic book, First-Order Logic, the notion of a Boolean valuation is central in motivating his analytical tableau proof system. Smullyan shows that these valuations are unique if they exist, and then he sketches an existence proof. In addition he suggests a possible computational procedure for finding a Boolean valuation, but it is not related to to the existence proof. A computer scientist would like to see the obvious explicit recursive algorithm for evaluating propositional formulas and a demonstration that the algorithm has the properties of a Boolean valuation. Ideally, the algorithm would be derived from the existence proof. It turns out to be unexpectedly difficult to find a natural existence proof from which the algorithm can be extracted, and it turns out that the implicit computational content of Smullyan's argument is not found where one might expect it. We show that using the notion of a very dependent function type, it is possible to specify the Boolean valuation and prove its existence constructively so that the natural recursive algorithm is extracted and is known to have the mathematically required properties by virtue of its construction. We illustrate all of these points using the Nuprl proof development system.

title: Database Preference Queries Revisited
abstract: In recent years, the database community has paid increasing attention to the formulation and treatment of preference queries. In this paper, we discuss a number of semantic and computational issues that preference queries raise. First, we examine the currently favored interpretation of such queries in database systems, showing that it is simply inappropriate semantically. Next, we suggest the ceteris paribus semantics as an appealing alternative that has long been accepted by economists and philosophers. Finally, we examine the computational problem of evaluating preference queries using the recently introduced operator BEST. We show that while BEST can be intractable given the ceteris paribus semantics, an appealing alternative, ORD, can be implemented efficiently for a wide class of preference queries.

title: Schema Meta-Matching

abstract: Schema matching is a basic operation in the data integration process, and several tools for automating it have been proposed and evaluated in the database community. While in many domains these tools succeed to find the right matching between concepts, empirical analysis shows that there is no single algorithm that is guaranteed to succeed in all possible domains. In this paper we introduce schema meta-matching, a novel framework for composing an arbitrary ensemble of algorithms for schema matching. Informally, schema meta-matching is about computing a "consensus" ranking of alternative mappings between two sets of concepts, given the "individual" graded rankings provided by several schema matching algorithms. We introduce several algorithms for this problem, varying from adaptations of some standard techniques for general quantitative rank aggregation, to novel techniques specific to the problem of schema matching, and to combinations of both.

title: Monadic Regions: Formal Type Soundness and Correctness
abstract: Drawing together two lines of research (that done in type-safe region-based memory management and that done in monadic encapsuation of effects), we give a type-preserving translation from a variation of the region calculus of Tofte and Talpin into an extension of System F augmented with monadic types and operations. Our source language is a novel region calculus, dubbed the Single Effect Calculus, in which sets of effects are specified by a single region representing an upper bound on the set. Our target language is F^RGN, which provides an encapsulation operator whose parametric type ensures that regions (and values allocated therein) are neither accessible nor visible outside the appropriate scope.

title: Feature-Based Textures
abstract: This paper introduces feature-based textures, a new image representation that combines features and texture samples for high-quality texture mapping. Features identify boundaries within a texture where samples change discontinuously. They can be extracted from vector graphics representations, or explicity added to raster images to improve sharpness. Texture lookups are then interpolated from samples while respecting these boundaries. We present results from a software implementation of this technique demonstrating quality, efficiency and low memory overhead.

title: Minimizing CVaR and VaR for a portfolio of derivatives
abstract: Value at risk (VaR) and conditional value at risk (CVaR) are the most frequently used risk measures in current risk management practice. As an alternative to VaR, CVaR is attractive since it is a coherent risk measure. We analyze the problem of computing the optimal VaR and CVaR portfolios. In particular, we illustrate that VaR and CVaR minimization problems for derivatives portfolios are typically ill-posed. For example, the VaR and CVaR minimizations based on delta-gamma approximations of the derivative values typically have an infinite number of solutions. In this paper, we focus on the portfolio selection problem which yields a portfolio of the minimum CVaR with a specified rate of return. We propose to include cost

as an additional preference criterion for the CVaR optimization problem. We demonstrate that, with the addition of a proportional cost, it is possible to compute an optimal CVaR derivative investment portfolio with significantly fewer instruments and comparable CVaR and VaR. A computational method based on a smoothing technique is proposed to solve a simulation based CVaR optimization problem efficiently. Comparison is made with the linear programming approach for solving the simulation based CVaR optimization problem.

title: Distributed Constraint-based Location Discovery in Ad hoc Networks
abstract: Location discovery is a fundamental building block for many mobile applications. Yet dedicated infrastructure for determining node locations is expensive, energy consuming, and simply unavailable under certain development scenarios. This paper presents an accurate,cheap and scalable protocol for location discovery. Called Zoom, this protocol operates by setting up and solving a system of geographic constraints based on connectivity information from the underlying communication network. Zoom achieves high accuracy by aggressively extracting constraints from the link layer, by propagating this information across multiple network hops and by explicitly tracking the set of possible locations for any given node instead of a single position estimate. Physical experiments with motes show that a large number(98%)of the nodes in a network can determine their positions based on a small number(30%)of landmark nodes with high accuracy(median error less than 30% of transmission range).

title: Scalable Extensibility via Nested Inheritance
abstract: Inheritance is a useful mechanism for factoring and reusing code. However, it has limitations for building extensible systems. We describe nested inheritance, a mechanism that addresses some of the limitations of ordinary inheritance and other code reuse mechanisms. Using our experience with an extensible compiler framework, we show how nested inheritance can be used to construct highly extensible software frameworks. The essential aspects of nested inheritance are formalized in a simple object-oriented language with an operational semantics and type system. The type system of this language is sound, so no run-time type checking is required to implement it and no run-time type errors can occur. We describe our implementation of nested inheritance as an unobtrusive extension of the Java language, called Jx. Our prototype implementation translates Jx code to ordinary Java code, without duplicating inherited code.

title: FDL: A Prototype Formal Digital Library
abstract: This manual describes the first prototype of a new kind of system which we call a Formal Digital Library (FDL). We designed the system and assembled the prototype as part of a research project sponsored by the Office of Naval Research entitled Building Interactive Digital Libraries of Formal Algorithmic Knowledge. A key purpose of the prototype library is to demonstrate that it is possible to build a system with many of the properties called for in the project proposal and to illustrate important scenarios for its use. Experience

with the prototype library will influence the design and construction of an improved system. The current prototype includes some expediences that made it possible to create a working system in less than a year. The prototype FDL is one part of the overall project. There are other theoretical and experimental efforts that are described in other publications. The library described here contains definitions, theorems, theories, proof methods, and articles about topics in computational mathematics and books assembled from them. Currently it supports these objects created with the theorem proving systems MetaPRL, Nuprl and PVS. We intend to include material from other implemented logics such as Minlog, Coq, HOL, Isabelle, and Larch in due course. In addition to the purely formal material, the Library supports mathematically literate hypertext articles that cite and use the formal concepts. These include explanations of reference algorithms and explanations of formal mathematical models used in applications. Many operations on the Library are automated and extensible. The basic operations are to find and read material, organize it, and submit new material. New operations can be defined algorithmically. This manual is intended to help users understand the operation of the Library and to demonstrate to those interested in the project what else we intended to build and how it will be used.

title: Natural Transformations as Rewrite Rules and Monad Composition
abstract: Eklund et al. (2002) present a graphical technique aimed at simplifying the verification of various category-theoretic constructions, notably the composition of monads. In this note we take a different approach involving string rewriting. We show that a given tuple (T,mu,eta) is a monad if and only if T is a terminal object in a certain category of functors and natural transformations, and that this fact can be established by proving confluence of a certain string rewriting system. We illustrate the technique on the monad composition problem of Eklund et al.

title: Efficient Inverted Lists and Query Algorithms for Structured Value Ranking in Update-Intensive Relational Databases
abstract: We propose a new ranking paradigm for relational databases called Structured Value Ranking (SVR). SVR uses {\em structured data values} to score (rank) the results of keyword search queries over text columns. Our main contribution is a new family of inverted list indices and associated query algorithms that can support SVR efficiently in update-intensive databases, where the structured data values (and hence the scores of documents) change frequently. Our experimental results on real and synthetic data sets using BerkeleyDB show that we can support SVR efficiently in relational databases.

title: Optimal Parameter Selection for Efficient Memory Integrity Verification Using Merkle Hash trees
abstract: A secure, tamper proof execution environment is critical for trustworthy network computing. Newly emerging hardware, such as those developed as part of the TCPA and Palladium initiatives, enables operating systems to implement such an environment through Merkle hash trees. We examine the selection of optimal

parameters, namely blocksize and tree depth, for Merkle hash trees based on the size of the memory region to be protected and the number of memory updates between updates of the hash tree. We analytically derive an expression for the cost of updating the hash tree, show that there is an optimal block size for the leaves of a Merkle tree for a given file size and update interval that minimizes the cost of update operations, and describe a general method by which the parameters of such a tree can be determined optimally.

title: Triggers over XML Views of Relational Data
abstract: Current systems that publish relational data as XML views are {\em passive} in the sense that they can only respond to user-initiated queries over the XML views. In this paper, we propose an {\em active} system whereby users can place triggers on (unmaterialized) XML views of relational data. In this architecture, we present scalable and efficient techniques for processing triggers over XML views by leveraging existing support for SQL triggers in commercial relational databases. We have implemented our proposed techniques in the context of the Quark system built on top of IBM DB2. Our performance results indicate that our proposed techniques are a feasible approach to supporting triggers over XML views of relational data.

title: P-Ring: An Index Structure for Peer-to-Peer Systems
abstract: Current peer-to-peer (P2P) index structures only support a subset of the desired functionality for P2P database systems. For instance, some P2P index structures support equality queries but not range queries, while others support range queries, but do not support multiple data items per peer or provide guaranteed search performance. In this paper, we devise a novel index structure called P-Ring that supports both equality and range queries, is fault-tolerant, provides guaranteed search performance, and efficiently supports large sets of data items per peer. We are not aware of any other existing index structure that supports all of the above functionality in a dynamic P2P environment. In a thorough experimental study we evaluate the performance of P-Ring and quantify the performance trade-offs of the different system components. We also compare P-Ring with two other P2P index structures, Skip Graphs and Chord.

title: Approximation Techniques for Spatial Data
abstract: Spatial Database Management Systems (SDBMS), e.g., Geographical Information Systems, that manage spatial objects such as points, lines, and hyper-rectangles, often have very high query processing costs. Accurate selectivity estimation during query optimization therefore is crucially important for finding good query plans, especially when spatial joins are involved. Selectivity estimation has been studied for relational database systems, but to date has only received little attention in SDBMS. In this paper, we introduce novel methods that permit high-quality selectivity estimation for spatial joins and range queries. Our techniques can be constructed in a single scan over the input, handle inserts and deletes to the database incrementally, and hence they can also be used for processing of streaming spatial data. In contrast to previous approaches,

our techniques return approximate results that come with provable probabilistic quality guarantees. We present a detailed analysis and experimentally demonstrate the efficacy of the proposed techniques.

title: A Lightweight Approach to Network Positioning
abstract: This paper describes a peer-to-peer overlay network for performing location-aware node and path selection in large-scale distributed systems. Our system, Meridian, provides a simple, lightweight and scalable framework for keeping track of location-information for participating nodes. The framework is based on local, relative coordinate systems in multi-resolution rings, direct measurement with scalable node-to-node handoff, and gossip protocols for dissemination. Large scale simulations and an implementation deployed on PlanetLab show that the framework can locate the closest node to given target with less than a 5ms median error, and the simplicity of the approach lends itself to a compact implementation.

title: Index Structures for Matching XML Twigs Using Relational Query Processors
abstract: Various index structures have been proposed to speed up the evaluation of XML path expressions. However, existing XML path indices suffer from at least one of three limitations: they focus only on indexing the structure (relying on a separate index for node content), or they are useful only for simple path expressions such as root-to-leaf paths, or they cannot be tightly integrated with a relational query processor. Moreover, there is no unified framework to compare these index structures. In this paper, we present a framework defining a family of index structures, including most existing XML path indices. We also propose two novel index structures in this family, with different space-time tradeoffs, that are effective for the evaluation of XML branching path expressions (i.e., twigs) with value conditions. We also show how this family of index structures can be realized using the access methods of the underlying database system. Finally, we present an experimental evaluation to understand the performance tradeoff between index space and twig matching time. The experimental results show that our novel indices achieve orders of magnitude improvement in performance for evaluating twig queries, albeit at a higher space cost, over the use of previously proposed XML path indices that can be tightly integrated with a relational query processor.

title: Correcting BLAST e-values for low-complexity segments
abstract: The statistical estimates of BLAST and PSI-BLAST are of extreme importance to determine the biological relevance of sequence matches. While being very effective in evaluating most matches, these estimates usually overestimate the significance of matches in the presence of low complexity segments. In this paper we present a model, based on divergence measures and statistics of the alignment structure, that corrects BLAST e-values for low complexity sequences without filtering or excluding them. We evaluate our method and compare it to other known methods using the Gene Ontology (GO)knowledge resource as a benchmark. Various performance measures, including ROC analysis, indicate that the new model improves over the state of the art. The program is available at biozon.org/ftp/ and www.cs.technion.ac.il/~itaish/lowcomp/

title: Distance Transforms of Sampled Functions
abstract: This paper provides linear-time algorithms for solving a class of minimization problems involving a cost function with both local and spatial terms. These problems can be viewed as a generalization of classical distance transforms of binary images, where the binary image is replaced by an arbitrary sampled function. Alternatively they can be viewed in terms of the minimum convolution of two functions, which is an important operation in grayscale morphology. A useful consequence of our techniques is a simple, fast method for computing the Euclidean distance transform of a binary image. The methods are also applicable to Viterbi decoding, belief propagation and optimal control.

title: Hierarchical Flow
abstract: This paper defines a hierarchical version of the maximum flow problem. In this model, the capacities increase over time and the resulting solution is a sequence of flows that build on each other incrementally. Thus far, hierarchical problems considered in the literature have been built on NP-complete problems. To the best of our knowledge, our results are the first to find a polynomial time problem whose hierarchical version is NP-complete. We present approximation algorithms and hardness results for many versions of

this problem, and comment on the relation to multicommodity flow.

title: X-Ray : Automatic Measurement of Hardware Parameters
abstract: There is growing interest in autonomic, self-tuning software that can optimize itself on new platforms, without manual intervention. Optimization requires detailed knowledge of the target platform such as the latency and throughput of instructions, the numbers of registers, and the organization of the memory hierarchy. An autonomic optimization system needs to determine such platform-specific information on its own. In this paper, we describe the design and implementation of X-Ray, which is a tool that automatically measures a large number of such platform-specific parameters. For some of these parameters, we also describe novel algorithms, which are more robust than existing ones. X-Ray is written in C for maximum portability, and it is based on accurate timing of a number of carefully designed micro-benchmarks. A novel feature of X-Ray is that it is easily extensible because it provides simple infrastructure and a code generator that can be used to produce the large number of micro-benchmarks needed for such measurements. There are few existing tools that address this problem. Our experiments show that X-Ray produces more accurate and more complete results than any of them.

title: Man vs. Machine : Comparing Handwritten and Compiler-generated Application-Level Checkpointing
abstract: The contributions of this paper are the following. We describe the implementation of the C^3 system for semi-automatic application-level checkpointing of C programs. The system has (i) a pre-compiler that instruments C programs so that they can save their states at program execution points specified by the user, and (ii) a novel memory allocator that manages the heap as a collection of pools. We describe two static analyses for reducing the overhead of saving and restoring the application state. The first one optimizes stack variables, while the second one optimizes heap data structures. To benchmark our system, we compare the overheads introduced by our semi-automatic approach with the overhead of handwritten application-level checkpointing in an n-body code written by Joshua Barnes. Except for very small problem sizes, these overheads are comparable. We highlight various algorithmic challenges in the optimization of application-level checkpointing that should provide grist for the mills of the PLDI community.

title: Region-Based Shape Analysis with Tracked Locations
abstract: This paper proposes a novel approach to shape analysis: using local reasoning about individual heap locations instead of global reasoning about entire heap abstractions. We present an inter-procedural shape analysis algorithm for languages with destructive updates and formulate it as a dataflow analysis. The key feature is a novel memory abstraction that differs from traditional abstractions in two ways. First, we build the shape abstraction and analysis on top of a pointer analysis. Second, we decompose the shape abstraction into a set of independent configurations, each of which characterizes one single heap location. Our approach:

1) leads to simpler algorithm specifications, because of local reasoning about the single location; 2) leads to efficient algorithms, because of the abstraction decomposition; and 3) makes it easier to develop context-sensitive, demand-driven, and incremental shape analyses. We have developed simple extensions that use the analysis results to find memory errors in programs with explicit deallocation, including memory leaks and accesses through dangling pointers. We have built a prototype system that implements the ideas in this paper and is designed to analyze C programs. Our experimental results support the intuition that local reasoning leads to more scalable analyses.

title: Think Globally, Search Locally
abstract: A key step in program optimization is the determination of optimal values for code optimization parameters such as cache tile sizes and loop unrolling factors. One approach, which is implemented in most compilers, is to use analytical models to determine these values. The other approach, used in library generators like ATLAS, is to perform a global search over the space of parameter values by generating different versions of the code and executing them on the actual machine to find the parameter values that give the best performance. Neither approach is suitable for use in general-purpose compilers that must generate high quality code for large programs running on complex architectures. Model-driven optimization may incur a performance penalty of 10-20\% even for a relatively simple code like matrix multiplication, as was shown recently by Yotov et al. On the other hand, global search is not tractable for optimizing large programs for complex architectures because the optimization space is too large. To address this problem, some researchers are exploring more sophisticated search algorithms such as the simplex method, but it remains to be seen if these methods are successful in reducing search time without compromising on the quality of the solution. In this paper, we advocate a different methodology for generating high-performance code without increasing search time dramatically. Our methodology has three components: (i) modeling, (ii) local search, and (iii) model refinement. We use analytical models to estimate optimal values for transformation parameters. Since it is impossible to build tractable analytical models that capture all the features of complex architectures, we advocate improving these estimates by using a local search in the neighborhood of the model-predicted values. Finally, if the performance gap between handwritten code and generated code is substantial on some architecture, we advocate model refinement. To demonstrate this methodology, we built a modified ATLAS system that used a simple analytical model and local search, and showed that on most architectures, the performance of the code produced by this system was comparable to that of code produced by the original ATLAS system using global search. However, on x86 architectures, the gap in performance was substantial, and could not be bridged by local search alone. We argue that the problem is that the model assumed aggressive operation scheduling to mask instruction latencies, but such scheduling can actually be harmful on x86 architectures, a somewhat surprising fact that does not appear to be known widely. To address this problem, we use model refinement to generate a more sophisticated model that, when combined with local search, enables the production of high-quality code on both RISC and CISC architectures.

title: Automatic Measurement of Memory Hierarchy Parameters
abstract: On modern computers, the running time of many applications is dominated by the cost of memory operations. To optimize such applications for a given platform, it is necessary to have a detailed

knowledge of the memory hierarchy parameters of that platform. In practice, this information is usually poorly documented if at all. Moreover, there is growing interest in self-tuning, autonomic software systems that can optimize themselves for different platforms, and these systems must determine memory hierarchy parameters automatically without human intervention. One solution is to use micro-benchmarks to determine the parameters of the memory hierarchy. In this paper, we argue that existing micro-benchmarks are inadequate, and present novel micro-benchmarks for determining the parameters of all levels of the memory hierarchy, including registers, all caches levels and the translation look-aside buffer. We have implemented these micro-benchmarks into an integrated tool that can be ported with little effort to new platforms. We present experimental results that show that this tool successfully determines memory hierarchy parameters on many current platforms, and compare its accuracy with that of existing tools.

title: Second-Order Abstract Interpretation via Kleene Algebra
abstract: Most standard approaches to the static analysis of programs, such as the popular worklist method, are first-order methods that inductively annotate program points with abstract values. In this paper we introduce a second-order approach based on Kleene algebra. In this approach, the primary objects of interest are not the abstract data values, but the transfer functions that manipulate them. These elements form a Kleene algebra. The dataflow labeling is not achieved by inductively labeling the program with abstract values, but rather by computing the star (Kleene closure) of a matrix of transfer functions. In this paper we introduce the method and prove soundness and completeness with respect to the standard worklist algorithm.

title: Kleene Algebra and Bytecode Verification
abstract: Most standard approaches to the static analysis of programs, such as the popular worklist method, are first-order methods that inductively annotate program points with abstract values. In a recent paper we introduced a second-order approach based on Kleene algebra. In this approach, the primary objects of interest are not the abstract data values, but the transfer functions that manipulate them. These elements form a Kleene algebra. The dataflow labeling is not achieved by inductively labeling the program with abstract values, but rather by computing the star (Kleene closure) of a matrix of transfer functions. In this paper we show how this general framework applies to the problem of Java bytecode verification.We show how to specify transfer functions arising in Java bytecode verification in such a way that the Kleene algebra operations (join, composition, star) can be computed efficiently. We also give a hybrid dataflow analysis algorithm that computes the closure of a matrix on a cutset of the control flow graph, thereby avoiding the recalculation of dataflow information along long paths. This method could potentially improve the performance over the standard worklist algorithm when a small cutset can be found.

title: An Empirical Comparison of Supervised Learning Algorithms Using Different Performance Metrics
abstract: We present the results of a large-scale empirical comparison between seven learning methods: SVMs,

neural nets, decision trees, memory-based learning, bagged trees, boosted trees, and boosted stumps. A novel aspect of our study is that we compare these methods on nine different performance criteria: accuracy, squared error, cross entropy, ROC Area, F-score, precision/recall break-even point, average precision, lift, and probability calibration. The models with the best performance overall are neural nets, SVMs, and bagged trees. However, if we apply Platt calibration to boosted trees, they become the best model overall. Detailed examination of the results shows that even the best models perform poorly on some problems or metrics, and that even the worst models sometimes yield the best performance.

title: Automatic Measurement of Hardware Parameters for Embedded Processors
abstract: Embedded processor designs are increasingly based on general-purpose processor families, modified and extended in various ways. However, the production of software for embedded processors remains a challenging problem. One promising approach for addressing this problem is self-optimizing software: instead of writing a program, one implements a program generator that produces a large number of program variants, and then determines empirically which variant performs best. The particular aspect of performance that is optimized can be execution time, power consumption, throughout, etc. To prevent a combinatorial explosion in the number of program variants that have to be considered, self-optimizing systems bound the search space by exploiting knowledge of hardware parameters such as the number of registers, the capacity of the L1 cache, etc. For software to be truly self-optimizing, hardware parameter values relevant for software optimization must be determined automatically. This paper makes the following contributions. We describe X-Ray - a robust and extensible micro-benchmark framework for measuring hardware parameters, in which it is very easy to implement new micro-benchmarks. This is particularly important in the embedded processor context because designers constantly add new features to architectures. We describe novel algorithms for measuring commonly used hardware parameters and show how they can be implemented in this framework. We evaluate our implementation experimentally on both embedded and desktop architectures, and show that it produces more accurate and complete results than existing tools.

title: Transforming the Academy: Knowledge Formation in the Age of Digital Information
abstract: Computer-mediated knowledge formation will profoundly change every academic discipline and pose fundamental challenges to the mission of the modern research university in teaching the new knowledge, securing sound methods for creating it, directing it to our deepest intellectual concerns, and insuring that we become wiser for it. Digital information, now measured in petabytes, is expanding rapidly; already most of it will never be examined by any human. Computers show us where to look and help us see patterns and extract meaning. How will this way of knowing impact the research university as the Age of Digital Information unfolds? To grasp the magnitude of the changes we face, it is important to realize that knowledge created with computer assistance goes well beyond classical knowledge formation rising from computer processing of digital information resources on a scale that could not be achieved by all peoples of the earth acting in concert using all their cognitive powers. Computers change the scale at which resources can be examined, and they already provide sufficient discriminatory powers that scale and speed compensate for their currently limited intelligence as they draw conclusions, make predictions, and participate in discoveries. The academy is not generally aware of the potential of this transformation, although some computer

scientists and computational scientist are. The challenge for society is to assimilate digital knowledge and to improve the human condition by its application. We also seek to understand how it will shape our sense of self, individually and collectively as a society and a culture. In all of these tasks, the universities play an indispensable role for which they must prepare.

title: Belief in Information Flow
abstract: Measurement of information flow requires a definition of leakage, which traditionally has been defined to occur when an attacker's uncertainty about secret data is reduced. We show that this uncertainty-based approach is inadequate for measuring information flow when an attacker is making assumptions about secret inputs and these assumptions might be incorrect. Moreover, we show that such attacker beliefs are an unavoidable aspect of any satisfactory definition of leakage. To reason about information flow based on beliefs, we develop a model that describes how an attacker's belief changes due to the attacker's observation of the execution of a probabilistic (or deterministic) program. The model leads to a new metric for quantitative information flow that measures accuracy rather than uncertainty of beliefs.

title: "Distance Estimation and Object Location via Rings of Neighbors"
abstract: We approach several problems on distance estimation and object location using a common technique called \emph{rings of neighbors}. Using this technique on metrics of low doubling dimension, we obtain significant improvements for low-stretch routing schemes, distance labeling, searchable small worlds, and triangulation-based distance estimation. Apart from improving the previously known bounds for these problems, our contributions include extending Kleinberg's small world model to metrics of low doubling dimension, and a short proof of the main result in [Chan et al., SODA'05]. Doubling dimension is a combinatorial (non-geometric) notion of dimensionality that has recently become popular in theoretical CS literature. A collection of rings of neighbors is a sparse distributed data structure that captures the distances and routing information. The idea is that every node u stores pointers to some nodes called 'neighbors'; these pointers are partitioned into several 'rings', so that for some increasing sequence of balls $\{B_i\}$ around u, the neighbors in the i-th ring lie inside B_i; the radii of these balls and the distribution of neighbors in a given ring depend on the specific application. For metrics of low doubling dimension it has been particularly helpful to combine the following two collections of rings: in the first collection, the cardinalities of the balls B_i grow exponentially, and the neighbors are distributed randomly; in the second collection the \emph{radii} of the B_i's grow exponentially, and the neighbors are distributed geographically. Although used implicitly in several contexts, rings of neighbors have not been articulated as a general proof technique.

title: Thwarting P2P Pollution Using Object Reputation
abstract: This paper describes a distributed object reputation management scheme that counteracts content pollution in peer-to-peer filesharing systems. The proposed scheme allows honest peers to assess the authenticity of online content by securely tabulating and managing endorsements from other peers. We employ a novel voter correlation scheme to weight the opinions of peers, which gives rise to favorable incentives and system dynamics. We present simulation results indicating that our system is scalable, efficient, and robust to attack.

title: Meridian: A Lightweight Framework for Network Positioning without Virtual Coordinates
abstract: Selecting nodes based on their position in the network is a basic building block for many distributed systems. This paper describes a peer-to-peer overlay network for performing position-based node selection. Our system, Meridian, provides a lightweight, accurate and scalable framework for keeping track of location information for participating nodes. The framework consists of an overlay network structured around multi-resolution rings, query routing with direct measurements, and gossip protocols for dissemination. We show how this framework can be used to address three commonly encountered problems in large-scale distributed systems without having to compute absolute coordinates; namely, closest node discovery, central leader election, and locating nodes that satisfy target latency constraints. We show analytically that the framework is scalable with logarithmic convergence when Internet latencies are modeled as a growth-constrained metric, a low-dimensional Euclidian metric, or a metric of low doubling dimension. Large scale simulations, based

on latency measurements from 6.25 million node-pairs, and an implementation deployed on PlanetLab both show that the framework is accurate and effective

title: Expressiveness and Performance of Full-Text Search Languages
abstract: We study the expressiveness and performance of full-text search languages. Our main motivation is to provide a formal basis for comparing such languages and todevelop a model for full-text search that can be tightly integrated withstructured search. We develop a formal model for full-text search based on thepositions of tokens (words) in the input text, and develop a full-text calculus(FTC) and a full-text algebra (FTA) with equivalent expressive power. Thissuggests a notion of completeness for full-text search languages and can be usedas a basis for a study of their expressiveness. We show that existing full-textlanguages are incomplete and develop {\tt COMP}, a complete full-text searchlanguage. We also identify practical subsets of {\tt COMP} that are morepowerful than existing languages, develop efficient query evaluation algorithmsfor these subsets, and study experimentally their performance.

title: Publication/Citation: A Proof-Theoretic Approach to Mathematical Knowledge Management
abstract: There are many real-life examples of formal systems that support constructions or proofs, but that do not provide direct support for remembering them so that they can be recalled and reused in the future. In this paper we examine the operations of publication (remembering a proof) and citation (recalling a proof for reuse), regarding them as forms of common subexpression elimination on proof terms. We then develop this idea from a proof theoretic perspective, describing a simple complete proof system for universal Horn equational logic using three new proof rules, publish, cite, and forget. These rules can provide a proof-theoretic infrastructure for proof reuse in any system.

title: End-to-End Availability Policies and Noninterference
abstract: This paper introduces the use of static information flow analysis for the specification and enforcement of end-to-end availability policies in programs. We generalize the decentralized label model, which is about confidentiality and integrity, to also include security policies for availability. These policies characterize acceptable risks by representing them as principals. We show that in this setting, a suitable extension of noninterference corresponds to a strong, end-to-end availability guarantee. This approach provides a natural way to specify availability policies and enables existing static dependency analysis techniques to be adapted for availability. The paper presents a simple language in which fine-grained information security policies can be specified as type annotations. These annotations can include requirements for all three major security properties: confidentiality, integrity, and availability. The type system for the language provably guarantees that any well-typed program has the desired noninterference properties, ensuring confidentiality, integrity, and availability.

title: Guaranteeing Correctness and Availability in P2P Range Indices
abstract: New and emerging P2P applications require sophisticated range query capability and also have strict requirements on query correctness, system availability and item availability. While there has been recent work on developing new P2P range indices, none of these indices guarantee correctness and availability. In this paper, we develop new techniques that can provably guarantee the correctness and availability of P2P range indices. We develop our techniques in the context of a general P2P indexing framework that can be instantiated with most P2P index structures from the literature. As a specific instantiation, we implement P-Ring, an existing P2P range index, and show how it can be extended to guarantee correctness and availability. We quantitatively evaluate our techniques using a real distributed implementation.

title: Multi-query optimization for sensor networks
abstract: The widespread dissemination of small-scale sensor nodes has sparked interest in a powerful new database abstraction for sensor networks: Clients "program" the sensors through queries in a high-level declarative language (such as a variant of SQL) permitting the system to perform the low-level optimizations necessary for energy-efficient query processing. In this paper we consider multi-query optimization for aggregate queries on sensor networks. We develop a set of distributed algorithms for processing multiple queries that incur minimum communication while observing the computational limitations of the sensor nodes. Our algorithms support incremental changes to the set of active queries and allow for local repairs to routes in response to node failures. A thorough experimental analysis shows that our approach results in significant energy savings, compared to previous work.

title: On the Use of Linear Programming for Unsupervised Text Classification
abstract: We present a new algorithm for large scale unsupervised text classification. Our method views each document as a sample of fixed size from a mixture model, and uses a novel L1-norm based theoretical approach due to Kleinberg and Sandler. We show that our algorithm performs extremely well on data sets of 10^5 documents and more, and in particular out-performs Latent Semantic Indexing by a large margin. Furthermore, on some tests its prediction accuracy approaches that of {\it supervised} learning with training set of 5,000 or more documents. Unlike LSI, our algorithm produces a ``well-behaved'' projection in general, that in many cases does not require additional clustering algorithm to separate topics. We experiment with the \arxiv - a collection of scientific abstracts and the \news~dataset - a small snapshot of 20 specific newsgroups.

title: A Measurement Study of a Publish Subscribe System
abstract: While publish-subscribe systems have attracted much research interest in the last decade, few established benchmarks have emerged and there has been little characterization of how they are used in practice. This paper examines RSS, a newly emerging, widely used publishsubscribe system for web micronews. Based on a trace study spanning 45 days at a medium-size academic department, and periodic polling of approximately 100,000 RSS feeds, we extract feed and client characteristics for RSS. We find that the popularity of RSS feeds follows a power law distribution. 16% of RSS feeds are updated hourly and 25% do not change at all during our polling period. 64%of all updates involve less than three lines in the XML document. We also find that RSS feed update sizes are proportional to feed size. Overall, an analysis of RSS, the first widely deployed publish-subscribe system, can help inform the design of next generation pub-sub systems.

title: Perils of Transitive Trust in the Domain Name System
abstract: The Domain Name System, DNS, is based on nameserver delegations, which introduce complex and subtle dependencies between names and nameservers. In this paper, we present results from a large scale survey of DNS that shows that these dependencies lead to a highly insecure naming system. We report specifically on three aspects of DNS security: the properties of the DNS trusted computing base, the extent and impact of existing vulnerabilities in the DNS infrastructure, and the ease with which attacks against DNS can be launched. The survey shows that a typical name depends on 46 servers on average, whose compromise can lead to domain hijacks, and names belonging to some countries depend on a few hundred nameservers. An attacker exploiting well-documented vulnerabilities in DNS can hijack more than 30% of the names appearing in the Yahoo and DMOZ.org directories. And certain nameservers, especially in educational institutions, control as much as 10% of the namespace.

title: Constrained Graphcut Texture Synthesis
abstract: This paper describes constrained graphcut texture synthesis (CGS), a graphcut-based synthesis algorithm that creates output textures satisfying constraints. We show that constrained texture synthesis can be posed in a principled way as an optimization problem that requires balancing two measures of quality: constraint satisfaction and texture seamlessness. We then present an efficient algorithm for finding good solutions to this problem, using generalized graphcut minimization. CGS enables explicit control while preserving the speed and quality benefits of graphcut texture synthesis. This approach supports the full image analogies framework, while providing superior image quality and performance. A range of applications of CGS are demonstrated, including detail synthesis, artistic filtering by analogy, and texture-by-numbers. CGS is easily extended to handle multiple constraints on a single output, thus enabling novel applications that combine both user-specified and image-based control.

title: A General Algebra and Implementation for Monitoring Event Streams
abstract: Recently there has been considerable research on Data Stream Management Systems (DSMS) to support analysis of data that arrives rapidly in high-speed streams. Most of these systems have very expressive query languages in order to address a wide range of applications. In this paper, we take a different approach. Instead of starting with a very powerful data stream query language, we begin with a well-known class of languages -- event languages. Through the addition of several simple, but powerful language constructs (namely parameterization and aggregates), we add pieces that extend their expressiveness towards full-fledged languages for processing data streams. Our resulting contributions are a novel algebra for expressing data stream queries, and a corresponding transformation of algebra expressions into finite state automata that can be implemented very efficiently. Our language is simple and natural, and it can express surprisingly powerful data stream queries. We formally introduce the language including a formal mapping of algebra expressions to finite state automata. Furthermore, we show the efficacy of our approach via an initial performance evaluation, including a comparison with the Stanford STREAM System.

title: Pre-Processing Environment Maps for Dynamic Hardware Shadows
abstract: Environment maps are a popular method of reproducing complex natural lighting. However, current methods for hardware environment map shadows depend on significant pre-computation and cannot support dynamic objects. This work presents a pre-process that decomposes an environment map into two components: a set of area lights and an ambient map. Once the map is split into these components, each is rendered with an appropriate mechanism. The area lights are rendered using an existing hardware-accelerated soft-shadow algorithm; for our implementation we use penumbra wedges. The ambient region is rendered using pre-integrated irradiance mapping. Using an NVidia 6800 on a standard desktop, we demonstrate high-quality environment map shadows for dynamic scenes at interactive rates.

title: Real-time Hardware-accelerated Relighting with Approximate Indirect Illumination
abstract: Deep framebuffer relighting engines are often used to speed up lighting design in geometricallycomplex procedurally-shaded environments where they provide interactive feedback on changes to the direct illumination. This paper presents an extension to these algorithms by providing real-time feedback for one-bounce indirect illumination. This is achieved by relighting a set of cached gather samples generated from the original geometry using a Monte Carlo gathering approach. To improve performance and decrease storage, the gather samples are clustered such that the resulting data structures are efficient for evaluation on modern GPUs. The hardware-accelerated implementation of our algorithm achieves real-time performance and is scalable to environments with high geometric and material complexity while supporting arbitrary direct lighting models, including local ones, and diffuse and glossy materials.

title: Relational Semantics of Local Variable Scoping
abstract: Most previous work on the equivalence of programs in the presence of local state has involved intricate memory modeling and the notion of contextual (observable) equivalence. We show how relational semantics can be used to avoid these complications. We define a notion of local variable scoping, along with a purely compositional semantics based on binary relations, such that all contextual considerations are completely encapsulated in the semantics. We then give an axiom system for program equivalence in the presence of local state that avoids all mention of memory or context and that does not use semantic arguments. The system is complete relative to the underlying flat equational theory. We also indicate briefly how the semantics can be extended to include higher-order functions.

title: An Incremental Model for Combinatorial Maximization Problems
abstract: Many combinatorial optimization problems aim to select a subset of elements of maximum value subject to certain constraints. We consider an incremental version of such problems, in which some of the constraints rise over time. A solution is a sequence of feasible solutions, one for each time step, such that later solutions build on earlier solutions incrementally. We introduce a general model for such problems, and define incremental versions of maximum flow, bipartite matching, and knapsack. We find that imposing an incremental structure on a problem can drastically change its complexity. With this in mind, we give general yet simple techniques to adapt algorithms for optimization problems to their respective incremental versions, and discuss tightness of these adaptations with respect to the three aforementioned problems.

title: Certified In-lined Reference Monitoring on .Net
abstract: MOBILE is an extension of the .NET Common Intermediate Language that permits certified In-Lined Reference Monitoring on Microsoft .NET architectures. MOBILE programs have the useful property that if they are well-typed with respect to a declared security policy, then they are guaranteed not to violate that security policy when executed. Thus, when an In-Lined Reference Monitor (IRM) is expressed in MOBILE, it can be certified by a simple type-checker to eliminate the need to trust the producer of the IRM.

MOBILE thereby permits development of arbitrarily complex IRM producers without contributing that added complexity to the trusted computing base of the system. Security policies in MOBILE are declarative, can involve potentially unbounded collections of objects allocated at runtime, and can regard finite- or infinite-length histories of security events exhibited by those objects. Our prototype implementation of MOBILE enforces properties expressed by finite-state security automata -- one automaton for each security-relevant object, and can type-check MOBILE programs in the presence of exceptions, finalizers, concurrency, and non-termination. Executing MOBILE programs requires no change to existing .NET virtual machine implementations, since MOBILE programs consist of normal managed CIL code with extra typing annotations stored in .NET attributes.

title: Optimal Resource Utilization in Content Distribution Networks
abstract: This paper examines replication in content distribution networks and proposes a novel mechanism for optimally resolving performance versus cost tradeoffs. The key insight behind our work is to formally and analytically capture the relationship between performance, bandwidth overhead and storage requirements for a web cache, express the system goals as a mathematical optimization problem, and solve for the optimal extent of replication that achieves the desired system goals with minimal overhead. We describe the design and implementation of a new content distribution network based on this concept, called CobWeb. CobWeb can achieve a target lookup latency while minimizing network and storage overhead, minimize access time while keeping bandwidth usage below a set limit, and alleviate “flash crowd” effects by rapidly replicating popular objects through fast and highly adaptive replica management. We outline the architecture of the CobWeb system, describe its novel optimization algorithm for intelligent resource allocation, and compare, through simulations and a physical deployment on PlanetLab, CobWeb’s informed, analysis-driven replication strategy to existing approaches based on passive caching and heuristics.

title: Static Score Bucketing in Inverted Indexes
abstract: Maintaining strict static score order of inverted lists is a heuristic used by search engines to improve the quality of query results when the entire inverted lists cannot be processed. This heuristic, however, increases the cost of index generation and requires time-consuming index build algorithms. In this paper, we study a new index organization based on static score bucketing. We show that this new technique significantly improves in index build performance while having minimal impact on the quality of search results. We also provide upper bounds on the quality degradation and verify experimentally the benefits of the proposed approach.

title: Corona: A High Performance Publish-Subscribe System for the World Wide Web
abstract: Despite the abundance of frequently changing information, the Web lacks a publish-subscribe interface for delivering updates to clients. The use of naive polling for update detection leads to poor

performance and limits scalability, as clients do not detect updates quickly and servers face high loads imposed by active polling. This paper describes Corona, a publish-subscribe system for the Web that provides high performance and scalability through optimal resource allocation. Users register interest in web pages through existing instant messaging services. Corona monitors the subscribed web pages, detects updates efficiently by allocating polling load among cooperating peers and disseminates them quickly to the clients. A distributed optimization engine ensures that Corona achieves the best update performance without exceeding load limits on content servers. Large scale simulations and measurements from Planet-Lab deployment, described in this paper, demonstrate that Corona achieves orders of magnitude improvement in update performance at a modest cost.

title: Implementing the Render Cache and the Edge-and-Point Image On Graphics Hardware
abstract: The render cache and the edge-and-point image (EPI) are techniques that permit high quality rendering at interactive rates of models illuminated with complex ray traced techniques, combining sparse sampling and discontinuities-respecting interpolation. The image reconstruction is decoupled from the samples generation process and permits the use of arbitrary shaders to gather shading samples. Although the system uses seemingly familiar graphics operations, their behavior differ in subtle and interesting ways from the regular graphics hardware use. This work presents a multi-pass rendering algorithm that brings the render cache and EPI image generation processes to programmable graphics hardware utilizing their newest capabilities. Its implementation permits substantial performance gains and leverages the CPU workload, allowing more time to be spent on the samples generation. It discusses the performance achieved, optimizations and limitations with the current generation hardware as well as possibilities for future improvements.

title: Heuristics Considered Harmful or Using Mathematical Optimization for Resource Management in Distributed Systems
abstract: Distributed systems often pose difficult to resolve resource management problems. These problems typically involve the partitioning of a critical resource, such as bandwidth, storage, or computational elements, between competing tasks. Traditionally, such problems are resolved using custom, domain-specific heuristics. Yet heuristics are neither robust to uctuations in load characteristics nor do they enable the system designer to reason definitively about the emergent properties of the system after deployment. In this paper, we argue

for a more principled approach to resource management in distributed systems. Namely, we propose that resource allocation problems are ideally suited for mathematical optimization. We outline a gen- eral approach based on analytical modeling, optimization, and practical implementation. We describe how we have applied this technique to several diverse domains, to yield qualitative improvements in performance and achieve strong guarantees.

title: An Experimental Study of the Skype Peer-to-Peer VoIP System
abstract: Despite its popularity, relatively little is known about the traffic characteristics of the Skype VoIP system and how they differ from other P2P systems. We describe an experimental study of Skype VoIP traffic conducted over a one month period, where over 30 million datapoints were collected regarding the population of online clients, the number of supernodes, and their traffic characteristics. The results indicate that although the structure of the Skype system appears to be similar to other P2P systems, particularly KaZaA, there are several significant differences in traffic. The number of active clients shows diurnal and work-week behavior, correlating with normal working hours regardless of geography. The population of supernodes in the system tends to be relatively stable; thus node churn, a significant concern in other systems, seems less problematic in Skype. The typical bandwidth load on a supernode is relatively low, even if the supernode is relaying VoIP traffic. The paper aims to aid further understanding of a signifi- cant, successful P2P VoIP system, as well as provide experimental data that may be useful for design and modeling of such systems. These results also imply that the nature of a VoIP P2P system like Skype differs fundamentally from earlier P2P systems that are oriented toward file-sharing, and music and video download applications, and deserves more attention from the research community.

title: Privacy via Pseudorandom Sketches
abstract: Imagine a collection of individuals who each possess private data that they do not wish to share with a third party. This paper considers how individuals may represent and publish their own data so as to simultaneously preserve their privacy and to ensure that it is possible to extract large-scale statistical behavior from the original unperturbed data. Existing techniques for perturbing data are limited by the number of users required to obtain approximate answers to queries, the richness of preserved statistical behavior, the privacy guarantees given and/or the amount of data that each individual must publish. This paper introduces a new technique to describe parts of an individual's data that is based on pseudorandom sketches. The sketches

guarantee that each individual's privacy is provably maintained assuming one of the strongest definitions of privacy that we are aware of: given unlimited computational power and arbitrary partial knowledge, the attacker can not learn any additional private information from the published sketches. However, sketches from multiple users that describe a subset of attributes can be used to estimate the fraction of users that satisfy any conjunction over the full set of negated or unnegated attributes. We show that the error of approximation is independent of the number of attributes involved and only depends on the number of users available. An additional benefit is that the size of the sketch is minuscule: $\lceil \log\log O(M)\rceil $ bits, where M is the number of users. Finally, we show how sketches can be combined to answer more complex queries.

title: Enabling Large Scale Coherency Among Mathematical Texts
abstract: Mathematical and program-code text is unique because significant portions of it can be anchored to counterparts in formal logical theories that are implemented by computer systems. These systems check formal proofs for correctness and trace logical dependencies among assertions. When elements of expository text, such as definitions and theorems, are formally linked to their implemented counterparts, we call the texts semantically anchored. Such texts exhibit considerable depth and authority. It is possible to leverage substantial investments made by governments, research laboratories, corporations, and universities in creating large collections of computerchecked and interactively-generated formal mathematics, making this research investment, these collections, accessible to an extended community of authors, researchers, students and teachers involved with mathematics. We advocate extending common authoring tools (text editors as opposed to formal proof development tools) so that they can easily produce semantically anchored documents suitable for dissemination along with the formal mathematics to which they are anchored; some texts would be newly authored, while others would be static textbased resources improved by anchoring. These tools will enable authors to create these documents by drawing on a large already existing and growing collection of formal material. We expect that anchored documents will enable interconnected collections where the computers support exact common reference among concepts and thus greatly facilitate collaborative contributions to online collections and provide large-scale coherency among mathematical texts.

title: A Graph-Based Approach towards Discerning Inherent Structures in a Digital Library of Formal Mathematics
abstract: As the amount of online formal mathematical content grows, for example through active efforts such

as the Mathweb [21], MOWGLI [4], Formal Digital Library, or FDL [1], and others, it becomes increasingly valuable to find automated means to manage this data and capture semantics such as relatedness and significance. We apply graph-based approaches, such as HITS, or Hyperlink-Induced Topic Search, [11] used for World Wide Web document search and analysis, to formal mathematical data collections. The nodes of the graphs we analyze are theorems and definitions, and the links are logical dependencies. By exploiting this link structure, we show how one may extract organizational and relatedness information from a collection of digital formal math. We discuss the value of the information we can extract, yielding potential applications in math search tools, theorem proving, and education.

title: Independence From Obfuscation: A Semantic Framework for Diversity
abstract: A set of replicas is diverse to the extent that all implement the same functionality but differ in their implementation details. Diverse replicas are less prone to having vulnerabilities in common, because attacks typically depend on memory layout and/or instruction-sequence specifics. Recent work advocates using mechanical means, such as program rewriting, to create such diversity. A correspondence between the specific transformations being employed and the attacks they defend against is often provided, but little has been said about the overall effectiveness of diversity per se in defending against attacks. With this broader goal in mind, we here give a precise characterization of attacks, applicable to viewing diversity as a defense, and also show how mechanically-generated diversity compares to a well-understood defense, strong typing.

title: Phase transitions and other phenomena in graphs grown with preferential attachment
abstract: We study a model of grown graph where a vertex is added at each time step, then an edge is added with probability δ. Callaway et al. showed that when both end vertices of the edge are chosen uniformly at random, the critical probability of edges δ_c to get a component which grows linearly with the number of vertices (a giant component) was \sfrac 1/8, smaller than in a comparable static graph. We derive a formula giving δ_c as a function of the initial self-attractiveness of vertices in a growth model where one end of the edge is chosen with preferential attachment. This number decreases even more as the self-attractiveness increases. For a self-attractiveness of one (value generally accepted for the web graph), it takes less than one edge for every twelve vertices to get a component whose size grows linearly with the number of vertices. This explains why graphs with more edges, such as the web-graph, or connectivity graphs of peer-to-peer networks, are so well connected and so well resilient to the deletion

of edges. We also show how to derive a formula giving the size of this giant component as function of the number of edges and the initial attractiveness.

title: Topology Search over Biological Databases
abstract: We introduce the notion of a data topology and the problem of topology search over databases. A data topology summarizes the set of all possible relationships that connect a given set of entities. Topology search enables users to search for data topologies that relate entities in a large database, and to effectively summarize and rank these relationships. Using topology search over a biological database, users can ask, for example, {\em how} transcription factor proteins are related to DNAs in humans. However, detecting topologies in large databases is a difficult problem because entities can be connected in multiple ways. In this paper, we formalize the notion of data topologies, develop efficient algorithms for computing data topologies based on user queries, and evaluate our algorithms using a real biological database.

title: Information-Flow Security for Interactive Programs
abstract: Interactive programs allow users to engage in input and output throughout execution. The ubiquity of such programs motivates the development of models for reasoning about their information-flow security, yet no such models seem to exist for imperative programming languages. Further, existing language-based security conditions founded on noninteractive models permit insecure information flows in interactive imperative programs. This paper formulates new strategy-based information-flow security conditions for a simple imperative programming language that includes input and output operators. The semantics of the language enables a fine-grained approach to the resolution of nondeterministic choices. The security conditions leverage this approach to prohibit refinement attacks while still permitting observable nondeterminism. Extending the language with probabilistic choice yields a corresponding definition of probabilistic noninterference. A soundness theorem demonstrates the feasibility of statically enforcing the security conditions via a simple type system. These results constitute a step toward understanding and enforcing information-flow security in real-world programming languages, which include similar input and output operators.

title: PTrie: Priority Queue based on multilevel prefix tree
abstract: Tree structures are very often used data structures. Among ordered types of trees there are many variants whose basic operations such as insert, delete, search, delete-min are characterized by logarithmic time complexity. In the article I am going to present the structure whose time complexity for each of the above operations is O(M/K + K), where M is the size of data type and K is constant properly matching the size of data type. Properly matched K will make the structure function as a very effective Priority Queue. The structure size linearly depends on the number and size of elements. PTrie is a clever combination of the idea of prefix tree -- Trie, structure of logarithmic time complexity for insert and delete operations, doubly linked list and queues.

title: Normalization of IZF with Replacement
abstract: IZF is a well investigated impredicative constructive version of Zermelo-Fraenkel set theory. Using set terms, we axiomatize IZF with Replacement, which we call IZF_R, along with its intensional counterpart IZF_R^-. We define a typed lambda calculus corresponding to proofs in IZF_R^- according to the Curry-Howard isomorphism principle. Using realizability for IZF_R^-, we show weak normalization of the calculus by employing a reduction-preserving erasure map from lambda terms to realizers. We use normalization to prove disjunction, numerical existence, set existence and term existence properties. An inner extensional model is used to show the properties for full, extensional IZF_R.

title: Latency- and Bandwidth-Minimizing Optimal Failure Detectors
abstract: Failure detectors are fundamental building blocks in distributed systems. Multi-node failure detectors, where the detector is tasked with monitoring other nodes, play a critical role in overlay networks and peer-to-peer systems. In such networks, failures need to be detected quickly and with low overhead. Achieving these properties simultaneously poses a difficult tradeoff between detection latency and resource consumption. In this paper, we examine this central tradeoff, formalize it as an optimization problem and analytically derive the optimal closed form formulas for multi-node failure detectors. We provide two variants of the optimal solution for optimality metrics appropriate for two different deployment scenarios. The latency-minimizing failure detector (LM-OFD) achieves the lowest average failure detection latency given a fixed bandwidth constraint for system maintenance. The bandwidth-minimizing failure detector (BM-OFD) will meet a desired detection latency target with the least amount of bandwidth consumed. We evaluate our optimal results with node lifetimes chosen from bimodal and power-law distributions, as well as real-world trace data from PlanetLab hosts that spans five months. Compared to standard failure detectors in wide use, our approach reduces failure detection latencies by 40% on average for the same bandwidth consumption, or conversely, reduce the amount of bandwidth consumed by 30% for the same failure detection latency.

title: Complexity Oblivious Network Management
abstract: Networks are hard to manage and in spite of all the so called holistic management packages, things are getting worse. We argue that this is an outcome of two fundamental flaws in the existing architecture: the management plane depends on the data plane and the complexity of the ever-evolving data plane encumbers the management plane. Consequently, addressing these flaws can make the network amenable to management. In this paper, we present Complexity Oblivious Network Management (CONMan), a network architecture in which the management plane does not depend on the data plane and all data plane protocols expose a generic management interface. This restricts the operational complexity of protocols to their implementation and allows the management plane to achieve high level policies in a structured fashion. Our preliminary experience with building the CONMan interface of a couple of protocols and using them for real world management tasks indicates the architecture's potential to alleviate the management troubles of the Internet.

title: Chunkyspread: Heterogeneous Unstructured End System Multicast
abstract: In order to maximize throughput in end-system multicast, it is necessary to have fine-grained control over the transmit load of each participating member. This both avoids bottlenecks where members are overloaded, and allows heterogeneous members to contribute as much transmit capacity as they are able or willing to. In this paper, we describe and simulate an unstructured endsystem multicast protocol called Chunkyspread that provides members with fine-grained control over their transmit load, scales well, has relatively low latencies, and can tolerate high membership churn. Chunkyspread is designed as a flexible framework that easily incorporates different constraints and optimizations. For instance, it is straightforward to add tit-for-tat or path disjointness as constraints to the system. This paper demonstrates the performance of Chunkyspread through extensive simulations, and provides partial validation of these simulations on Emulab. It also provides detailed comparisons with Splitstream, a structured heterogeneous end-system multicast protocol. The simulations show that Chunkyspread provides far better control over transmit load than Splitstream, while exhibiting comparable or better latency and responsiveness to churn.

title: An Experiment in Deploying Next Generation Network Protocols
abstract: This paper presents IP(dmux) - a network-layer infrastructure that serves as a general-purpose deployment vehicle for next-generation network protocols. For each new network protocol, IP(dmux) provides a network-level access path between any end-user and the (approximately) closest router supporting the new protocol. IP(dmux) thus ensures that even partial deployments of new protocols are easily accessible by the global Internet user population. We present the design and implemention of IP(dmux) which we then use to experiment with three next-generation IP architectures - IPv6, FRM (a new protocol for global network-layer multicast) and i3 (a rendezvous-based network architecture). Our experiences suggest new networklayer architectures can easily leverage IP(dmux) to aid their deployment. Moreover, our evaluation through simulation, measurement and wide-area deployment indicates that even small-sized IP(dmux) deployments can yield reasonable endto- end performance for partially deployed next generation architectures.

title: Understanding IP Anycast
abstract: In this paper we present the first detailed analysis of IP anycast as used in the anycasting of the root-servers. The main results of our study are: The anycasting of an IP prefix does not have any unfavorable interactions with the routing system. Hence, IP anycast offers very good affinity2 - this alleviates concerns regarding running connection oriented services on top of anycast. IP Anycast, by itself, does not offer proximity in terms of metrics such as latency. IP Anycast's backwards compatibility derives from the fact that it is transparent to existing routing protocols, but this transparency also implies that in many cases inter-domain routing, which was designed with unicast path-selection in mind, chooses anycast locations which are not close to the source. We also present deployment schemes 1the problems include scalability by the number of anycast groups, difficulty of deployment etc.; these have restricted the use of IP anycast to critical infrastructure services 2tendency of subsequent packets of a connection to be delivered to the same target that might allow anycast to achieve good latency based proximity

title: An Axiomatization of Arrays for Kleene Algebra with Tests
abstract: The formal analysis of programs with arrays is a notoriously difficult problem due largely to aliasing considerations. In this paper we augment the rules of Kleene algebra with tests (KAT) with rules for the equational manipulation of arrays in the style of schematic KAT. These rules capture and make explicit the essence of subscript aliasing, where two array accesses can be to the same element. We prove the soundness of our rules, as well as illustrate their usefulness with several examples, including a complete proof of the correctness of heapsort.

title: What's "Next"?
abstract: Event processing systems have wide applications ranging from monitoring RSS feeds to managing events from RFID readers, and there exists much work on them in the literature. Many competing temporal models for event systems have been proposed, with no consensus on which approach is best. In this paper we determine the important properties for such temporal models. Our approach is to define a very general

temporal model capable of representing time in all of the major event systems. We introduce axioms motivated by the time stamp ordering relation and the semantics of the successor operator, which is present in all event systems. Only two of our axioms are controversial; the remaining axioms are satisfied by all event systems. We consider the temporal models obtained using our full set of axioms, and the models that result when one or the other of our controversial axioms is weakened. In one case we see that there is no acceptable temporal model. In the other two cases, we show that the resulting temporal model is effectively unique up to isomorphism, leaving us with only two different models. Finally, we argue that one of the two models is better than the other when both naturalness of semantics and efficiency of implementation are considered.

title: An Incremental Model for Combinatorial Minimization
abstract: Traditional optimization algorithms are concerned with static input, static constraints, and attempt to produce static output of optimal value. Recent literature has strayed from this conventional approach to deal with more realistic situations in which the input changes over time. Incremental optimization is a new framework for handling this type of dynamic behavior. We consider a general model for producing incremental versions of traditional covering problems along with several natural incremental metrics. Using this model, we demonstrate how to convert conventional algorithms into incremental algorithms with only a constant factor loss in approximation power. We introduce incremental versions of min cut, edge cover, and (k, r)-center and present some hardness results. Lastly, we discuss how the incremental model can help us more fully understand online problems and their corresponding algorithms.

title: Network Distance Estimation with Guarantees for All Node Pairs
abstract: An active line of research in the networking community studies the distance matrix defined by the node-to-node latencies in the Internet and, in particular, provides a number of quite successful distributed approaches that approximately reconstruct these distances from observations. In such algorithms it is feasible to measure distances among only a linear or near-linear number of node pairs; the rest of the distances are simply not available. The most common framework for Internet measurements of this type is a beacon-based approach: one chooses randomly a constant number of nodes ('beacons') in the network, each node measures its distance to all beacons, and one then has access to only these measurements for the remainder of the algorithm. To obtain theoretical insight into these recent Internet measurement studies, [Kleinberg et al. FOCS'04] formulated a concrete distance reconstruction problem, termed "triangulation", where distances from a given node to beacons form a short node label, and the unobserved distances are inferred from these labels using triangle inequality. While several significant results have been obtained in this framework, all these results include a notion of slack: they provide no guarantees for a small fraction of node pairs. Essentially, for any given positive ϵ and δ, one can reconstruct all but an ϵ-fraction of distances with multiplicative error at most $1+\delta$, using only a constant number of beacons. In this paper we obtain triangulation-style guarantees \emph{for all node pairs}: we reconstruct all distances with multiplicative error at most $1+\delta$, with only a poly-logarithmic load on each participating node. Our guarantees are for growth-constrained metrics, a well-studied family of metrics which have been proposed as a reasonable abstraction of Internet latencies.

title: Octant: A Comprehensive Framework for the Geolocalization of Internet Hosts
abstract: This paper outlines a novel, comprehensive framework for geolocalization, that is, determining the physical location of Internet hosts based on network measurements. The core insight behind this framework is to pose the geolocalization problem formally as one of error-minimizing constraint satisfaction, to create a system of constraints by deriving them aggressively from network measurements, and to solve the system using cheap and accurate geometric methods. The framework is general and accommodates both positive and negative constraints, that is, constraints on where the node can or cannot be, respectively. It can reason in the presence of uncertainty, enabling it to gracefully cope with aggressively derived constraints that may contain errors. Since the solution space is represented geometrically as a region bounded by Bezier curves, the framework yields an accurate set of all points where the target may be located. Preliminary results on PlanetLab show promise; the framework can localize the median node to within 22 mi., a factor of three better than previous approaches, with little error.

title: Selection and Analysis of Minimal Sets of Enzyme Levels and Regulatory Structures for Optimization of Microbial Overproduction Using Large-Scale Kinetic Models of Cellular Systems
abstract: We introduce a hybrid deterministic/stochastic optimization modeling framework to identify minimal sets of enzyme levels and enzyme regulatory structures to meet significant overproduction requirements using large-scale kinetic models of microbial metabolism and essential protein machinery. Specifically, a simulated annealing algorithm is used to navigate through the discrete space of enzyme levels and regulatory structures, while a sequential quadratic programming method is utilized to identify optimal enzyme levels and regulatory kinetic parameters. The framework is demonstrated on a large-scale and chemically-detailed kinetic model of central metabolism in Escherichia coli (wild-type strain W3110) for the optimization of the glucose uptake through the phosphotransferase system (PTS) and serine biosynthesis. Computational results show that by optimally modulating enzyme levels and carefully altering enzyme regulatory properties, a stable 8-fold increase in the PTS uptake rate and a stable 22-fold increase in serine biosynthesis can be achieved. Importantly, substantial improvements in the targeted fluxes can be predicted by manipulating only small subsets of enzyme levels and regulatory structures. For example, the modulation of only three enzyme levels leads to a flux increase, which is almost 50% of the best predictions, and the manipulation of only six enzyme levels already leads to a flux increase of 80% of the best predictions. Remarkably, by optimally modulating 10 enzyme levels, the total central metabolism's enzyme overexpression capability is reached and any further increase in the targeted fluxes can be only possible if the pathway regulation is additionally altered, though at the expense of the loss of the pathway's steady state stability properties (i.e., no steady state can exist or oscillatory regimes may be encountered). The developed framework has also demonstrated a strong synergism between the redesign of control architectures for tightly regulated reaction steps (e.g., phosphofructokinase) and the overexpression of those enzymes which lack any type of regulatory properties (e.g., glyceraldehyde-3-phosphate dehydrogenase). Although the nonlinear optimization predictions are found in a good agreement with Metabolic Control Analysis (MCA) and large control coefficients can be indicative of the corresponding "rate limiting" enzymes and critical feedback regulatory parameters, the non-linear stable optimization predictions could not be found from the MCA alone. The proposed optimization framework

thus provides a new versatile modeling strategy and computational tool for systematic optimal elucidation of minimal sets of controlling enzymes and their critical regulatory properties with broad implication in biotechnological studies.

title: Characterization of XML Functional Dependencies and their Interaction with DTDs
abstract: With the rise of XML as a standard model of data exchange, XML functional dependencies (XFDs) have become important to areas such as key analysis, document normalization, and data integrity. XFDs are more complicated than relational functional dependencies because the set of XFDs satisfied by an XML document depends not only on the document values, but also the tree structure and corresponding DTD. In particular, constraints imposed by DTDs may alter the implications from a base set of XFDs, and may even be inconsistent with a set of XFDs. In this paper we examine the interaction between XFDs and DTDs. We present a sound and complete axiomatization for XFDs, both alone and in the presence of certain classes of DTDs. We show that these DTD classes form an axiomatic hierarchy, with the axioms at each level a proper superset of the previous. Furthermore, we show that consistency checking with respect to a set of XFDs is feasible for these same classes.

title: Making Distributed Computation Trustworthy by Construction
abstract: Trustworthy computing systems must provide data confidentiality and data integrity, and must be available. This paper shows that these security properties can be provided by construction, by compiling high-level, security-typed source code into explicitly distributed, security-typed target code. This code transformation provably preserves the confidentiality, integrity, and availability properties of the source. A key technical contribution is the new target language, which describes distributed computation. In this language, any well-typed program satisfies noninterference properties that ensure confidentiality and integrity. Further, the language supports the distribution and replication of code and data using quorum replication, which enables simultaneous enforcement of integrity and availability. A novel timestamp scheme handles out-of-order accesses by concurrent distributed threads without creating covert channels.

title: Distance Estimation and Object Location via Rings of Neighbors
abstract: We consider four problems on distance estimation and object location which share the common flavor of capturing global information via informative node labels: low-stretch routing schemes, distance labeling, searchable small worlds, and triangulation-based distance estimation. Focusing on metrics of low doubling dimension, we approach these problems with a common technique called "rings of neighbors", which refers to a sparse distributed data structure that underlies all our constructions. Apart from improving the previously known bounds for these problems, our contributions include extending Kleinberg's small world model to doubling metrics, and a short proof of the main result in [Chan et al., SODA 2005]. Doubling dimension is a notion of dimensionality for general metrics that has recently become a useful algorithmic

concept in the theoretical computer science literature.

title: Linear Time Algorithms Based on Multilevel Prefix Tree for Finding Shortest Path with Positive Weights and Minimum Spanning Tree in a Networks
abstract: In this paper I present general outlook on questions relevant to the basic graph algorithms; Finding the Shortest Path with Positive Weights and Minimum Spanning Tree. I will show so far known solution set of basic graph problems and present my own. My solutions to graph problems are characterized by their linear worst-case time complexity. It should be noticed that the algorithms which compute the Shortest Path and Minimum Spanning Tree problems not only analyze the weight of arcs (which is the main and often the only criterion of solution hitherto known algorithms) but also in case of identical path weights they select this path which walks through as few vertices as possible. I have presented algorithms which use priority queue based on multilevel prefix tree -- PTrie. PTrie is a clever combination of the idea of prefix tree -- Trie, the structure of logarithmic time complexity for insert and remove operations, doubly linked list and queues. In C++ I will implement linear worst-case time algorithm computing the Single-Destination Shortest-Paths problem and I will explain its usage.

title: Metric Embeddings with Relaxed Guarantees
abstract: We consider the problem of embedding finite metrics with "slack": we seek to produce embeddings with small dimension and distortion while allowing a (small) constant fraction of all distances to be arbitrarily distorted. This definition is motivated by recent research in the networking community, which achieved striking empirical success at embedding Internet latencies with low distortion into low-dimensional Euclidean space, provided that some small slack is allowed. Answering an open question of [Kleinberg, Slivkins, and Wexler, IEEE FOCS 2004], we show that provable guarantees of this type can in fact be achieved in general: any finite metric can be embedded, with constant slack and constant distortion, into constant-dimensional Euclidean space. We then show that there exist stronger embeddings into L1 which exhibit "gracefully degrading" distortion: these is a single embedding into L1 that achieves distortion at most O(log 1/epsilon) on all but at most an epsilon-fraction of distances, *simultaneously* for all epsilon greater than 0. We extend this with distortion O(log 1/epsilon)^{1/p} to maps into general Lp, p greater than or equal to 1 for several classes of metrics, including those with bounded doubling dimension and those arising from the shortest-

path metric of a graph with an excluded minor. Finally, we show that many of our constructions are tight, and give a general technique to obtain lower bounds for epsilon-slack embeddings from lower bounds for low-distortion embeddings.

title: Getting the Most Out of Ensemble Selection
abstract: We investigate four previously unexplored aspects of ensemble selection, a procedure for building ensembles of classifiers. First we test whether adjusting model predictions to put them on a canonical scale makes the ensembles more effective. Second, we explore the performance of ensemble selection when different amounts of data are available for ensemble hillclimbing. Third, we quantify the benefit of ensemble selection's ability to optimize to arbitrary metrics. Fourth, we study the performance impact of pruning the number of models available for ensemble selection. Based on our results we present improved ensemble selection methods that double the benefit of the original method.

title: Cluster Ensembles for Network Anomaly Detection
abstract: Cluster ensembles aim to find better, more natural clusterings by combining multiple clusterings. We apply ensemble clustering to anomaly detection, hypothesizing that multiple views of the data will improve the detection of attacks. Each clustering rates how anomalous a point is; ratings are combined by averaging or taking either the minimum, the maximum, or median score. The evaluation shows that taking the median prediction from the cluster ensemble results in better performance than single clusterings. Surprisingly, averaging the individual predictions a) leads to worse performance than that of individual clusterings, and b) performs identically to taking the minimum prediction from the ensemble. This counter-intuitive result stems from asymmetric prediction distributions.

title: Maintaining Structural Invariants in Shape Analysis with Local Reasoning

abstract: This paper presents a novel shape analysis algorithm with local reasoning that is designed to analyze heap structures with structural invariants, such as doubly-linked lists. The algorithm abstracts and analyzes one single heap cell at a time. In order to maintain the structural invariants, the analysis uses a local heap abstraction that models the sub-heap consisting of one cell and its immediate neighbors. The proposed algorithm can successfully analyze standard doubly-linked list manipulations.

title: Meta Clustering
abstract: Clustering is ill-defined. Unlike supervised learning where labels lead to crisp performance criteria such as accuracy and squared error, clustering quality depends on how the clusters will be used. Devising clustering criteria that capture what users need is difficult. Most clustering algorithms search for one optimal clustering based on a pre-specified clustering criterion. Once that clustering has been determined, no further clusterings are examined. Our approach differs in that we search for many alternate reasonable clusterings of the data, and then allow users to select the clustering(s) that best fit their needs. Any reasonable partitioning of the data is potentially useful for some purpose, regardless of whether or not it is optimal according to a specific clustering criterion. Our approach first finds a variety of reasonable clusterings. It then clusters this diverse set of clusterings so that users must only examine a small number of qualitatively different clusterings. In this paper, we present methods for automatically generating a diverse set of alternate clusterings, as well as methods for grouping clusterings into meta clusters. We evaluate meta clustering on four test problems, and then apply meta clustering to two case studies. Surprisingly, clusterings that would be of most interest to users often are not very compact clusterings.

title: Worst-Case Background Knowledge in Privacy
abstract: Recent work has shown the necessity of considering an attacker's background knowledge when reasoning about privacy in data publishing. However, in practice, the data publisher does not know what background knowledge the attacker possesses. Thus, it is important to consider the worst-case. In this paper, we initiate a formal study of worst-case background knowledge. We propose a language that can express any background knowledge about the data. We provide a polynomial time algorithm to measure the amount of disclosure of sensitive information in the worst case, given that the attacker has at most k pieces of information in this language. We also provide a method to efficiently sanitize the data so that the amount of disclosure in the worst case is less than a specified threshold.

title: A Normalizing Intuitionistic Set Theory with Inaccessible Sets
abstract: We propose a set theory strong enough to interpret powerful type theories underlying proof assistants such as LEGO and also possibly Coq, which at the same time enables program extraction from constructive proofs. For this purpose, we axiomatize impredicative constructive version of Zermelo-Fraenkel set theory IZF with Replacement and ω-many inaccessibles, which we call IZF_{R\omega}. Our axiomatization

of IZF_{R\omega} utilizes set terms, an inductive definition of inaccessible sets and mutually recursive nature of equality and membership relations. It allows us to define a weakly-normalizing typed lambda calculus \ lambda Z_\omega corresponding to proofs in IZF_{R\omega} according to the Curry-Howard isomorphism principle. We use realizability to prove the normalization theorem, which provides basis for extracting programs from IZF_{R\omega} proofs.

title: Birthdays, Broadcasts, and Boolean Algebras: Probabilistic Boolean Algebras and Applications
abstract: In the area of extremal finite set theory there are many combinatorial results concerning the selection of m k-element sets. This type of set selection can also be viewed as a boolean algebra. In this paper we consider a probabilistic construction of this boolean algebra, concentrating on the structure and properties such an algebra may form, particularly the structure of the algebra's atoms. The results are then applied to a generalization of the popular birthday problem, where the event of interest is now whether all selected sets have a unique element; we find an upper bound on the probability of this event. We also extend the definition of the generalized birthday problem to model content protection protocols. While these protocols are widely used in digital media rights management, they are insufficiently analyzed due to a lack of such an underlying model. We focus on the event that revoking the rights of multiple pirate users inadvertently causes the rights of other, authorized users to be unjustly revoked; we give an exact formula for the probability of this event.

title: Topology Search over Biological Databases Topology Search over Biological Databases
abstract: We introduce the notion of a data topology and the problem of topology search over databases. A data topology summarizes the set of all possible relationships that connect a given set of entities. Topology search enables users to search for data topologies that relate entities in a large database, and to effectively summarize and rank these relationships. Using topology search over a biological database, users can ask, for example, {\em how} transcription factor proteins are related to DNAs in humans. However, detecting topologies in large databases is a difficult problem because entities can be connected in multiple ways. In this paper, we formalize the notion of data topologies, develop efficient algorithms for computing data topologies based on user queries, and evaluate our algorithms using a real biological database.

title: TRUST-TECH based Neural Network Training
abstract: Supervised learning using artificial neural networks has numerous applications in various domains of science and engineering. Efficient training mechanisms in a neural network play a vital role in deciding the network architecture and the accuracy of the classifier. Most popular training algorithms tend to be greedy and hence get stuck at the nearest local minimum of the error surface. To overcome this problem, some global methods (like multiple restarts, genetic algorithms, simulated annealing etc.) for efficient training make use of stochastic approaches in combination with local methods to obtain an effective set of training parameters.

Due to the stochastic nature and lack of effective fine tuning capability, these algorithms often fail to obtain an optimal set of training parameters. In this paper, a new method to improve the subspace parameter search capability of training algorithms is proposed. This new method takes advantage of TRUST-TECH (TRansformation Under STability-reTaining Equilibrium CHaracterization) to compute neighborhood local minimum of the error surface. The proposed approach obtains multiple local optimal solutions surrounding the current local optimal solution in a systematic manner. Empirical results on different machine learning datasets indicate that the proposed algorithm outperforms current algorithms available in the literature.

title: Memory Leak Analysis by Contradiction
abstract: We present a novel leak detection algorithm. To prove the absence of a memory leak, the algorithm assumes its presence and runs a backward heap analysis to disprove this assumption. We have implemented this approach in a memory leak analysis tool and used it to analyze several routines that manipulate linked lists and trees. Because of the reverse nature of the algorithm, the analysis can locally reason about the absence of memory leaks. We have also used the tool as a scalable, but unsound leak detector for C programs. The tool has found several bugs in larger programs from the SPEC2000 suite.

title: Firebreak: An IP Perimeter Defense Architecture
abstract: After many years of research, the Distributed Denial of Service (DDoS) problem remains essentially unsolved, both in industry and in research. Industry solutions rely primarily on beefing up the bandwidth near the attack target, and/or on intercepting traffic at proxies while keeping the target IP address secret. The former approach is expensive, and the latter amounts to "security through obscurity". Existing research solutions, on the other hand, have so far proven economically infeasible. We propose an architecture, called the firebreak, based on IP-level indirection. With firebreak, target IP addresses are simply unreachable from ISP customer networks and endhosts. Rather, IP packets are addressed to proxies deployed near the edge using IP anycast, and from there are tunneled using the target IP addresses. This use of IP indirection, as well as the use of IP anycast and tunneling to deploy firebreak, is the main research contribution of firebreak. This paper describes the firebreak architecture, discusses its pros and cons, and suggests directions for future work

title: Properties Framework and Typed Endpoints for Scalable Group Communication
abstract: Group communication is a powerful tool that simplifies the development of dependable systems, but widespread adoption of the paradigm has been limited. The main problem is that existing systems lack important forms of scalability and clean OS embeddings that can sustain high performance. QuickSilver is a new platform designed to enable casual use of groups on a massive scale. Our approach relies on a new way of constructing hierarchical, scalable protocols. Groups are accessed via typed communication endpoints; an underlying properties framework promotes flexibility and modularity.

title: The Power of Indirection: Achieving Multicast Scalability by Mapping Groups to Regional Underlays
abstract: Reliable multicast is a powerful primitive, useful for data replication, event notification (publish-subscribe), fault tolerance and other purposes. Yet many of the most interesting applications give rise to huge numbers of heavily overlapping groups, some of which may be large. Existing multicast systems scale scale poorly in one or both respects. We propose the QuickSilver Scalable Multicast protocol (QSM), a novel solution that delivers performance almost independent of the number of groups and introduces newmechanisms that scale well in the number of nodes with minimal performance and delay penalties when loss occurs. Key to the solution is a level of indirection: a mapping of groups to regions of group overlap in which communication associated with different protocols can be merged. The core of QSM is a new regional multicast protocol that offers scalability and performance benefits over a wide range of region sizes.

title: Securing BGP Using External Security Monitors
abstract: Security modifications to legacy network protocols are expensive and disruptive. This paper outlines an approach, based on external security monitors, for securing legacy protocols by deploying additional hosts that locally monitor the inputs and outputs of each host executing the protocol, check the behavior of the host against a safety specification, and communicate using an overlay to alert other hosts about invalid behavior and to initiate remedial actions. Trusted computing hardware provides the basis for trust in external security

monitors. This paper applies this approach to secure the Border Gateway Protocol, yielding an external security monitor called N-BGP. N-BGP can accurately monitor a BGP router using commodity trusted computing hardware. Deploying N-BGP at a random 10% of BGP routers is sufficient to guarantee the security of 80% of Internet routes where both endpoints are monitored by N-BGP. Overall, external security monitors secure the routing infrastructure using trusted computing hardware and construct a security plane for BGP without having to modify the large base of installed routers and servers.

title: Identity Trail: Covert Surveillance Using DNS
abstract: The Domain Name System (DNS) was originally designed with the assumption that the DNS will return the same answer to any given query regardless of who may have issued the query, and that all data in the DNS is thus visible. Such an assumption can no longer be justified for private Internet hosts, particularly mobile laptops and PDAs. IP addresses in the DNS reveal a host's geographic location and corporate affiliation to anyone that is interested without the host's knowledge or consent. This paper identifies an attack that allows anyone on the Internet to covertly monitor mobile devices to construct detailed profiles including user identity, daily commute patterns, and travel itineraries. We identify a growing number of users vulnerable to this attack (two million and climbing), and covertly monitor over one hundred thousand of them. We demonstrate the feasibility and severity of such an attack in today's Internet. We further propose shortterm and long-term defenses for the attack.

title: Stability Region based Methods for Learning and Discovery
abstract: Many problems that arise in machine learning and data mining domains deal with nonlinearity and quite often demand users to obtain global optimal solutions rather than local optimal ones. Several algorithms had been proposed in the optimization literature and inherited by the machine learning community. Popularly known as the {\it initialization problem}, the ideal set of parameters required will significantly depend on the initial values given by the user. In this paper, we propose stability region based methods for systematically exploring the subspace of the parameters to obtain the neighborhood local optimal solutions. The proposed algorithm takes advantage of TRUST-TECH (TRansformation Under STability-reTaining Equilibria CHaracterization) to compute neighborhood local optimal solutions on the nonlinear surface in a systematic manner using stability regions. Our method explores the dynamic and geometric characteristics of stability boundaries of a nonlinear dynamical system corresponding to the nonlinear function of interest. Basically, our method coalesces the advantages of the traditional local optimizers with that of the dynamic and geometric characteristics of the stability regions of the corresponding nonlinear dynamical system of the log-likelihood function. Two phases namely, the local phase and the stability region phase, are repeated alternatively in the parameter space to achieve improvements in the quality of the solutions. The local phase obtains the local maximum of the nonlinear function and the stability region phase helps to escape out of the local maximum by moving towards the neighboring stability regions. The stability region based algorithms are applied to three important machine learning problems in: (1) Unsupervised learning - model-based clustering, (2) Pattern discovery - motif finding problem and (3) Supervised learning - training artificial neural networks. Our algorithms were tested on both synthetic and real datasets and the advantages of using this stability region based framework are clearly manifested. This framework not only reduces the sensitivity

to initialization, but also allows the flexibility for the practitioners to use various global and local methods that work well for a particular problem of interest.

title: Automatic Proof Generation in Kleene Algebra with Tests
abstract: Kleene algebra (KA) is the algebra of regular events. Familiar examples of Kleene algebras include regular sets, relational algebras, and trace algebras. A Kleene algebra with tests (KAT) is a Kleene algebra with an embedded Boolean subalgebra. The addition of tests allows one to encode while programs as KAT terms, thus the equational theory of KAT can express (propositional) program equivalence. More complicated statements about programs can be expressed in the Hoare theory of KAT, which suffices to encode Propositional Hoare Logic. In this paper, we prove the following results. First, there is a PSPACE transducer which takes equations of Kleene Algebra as input and outputs Hilbert-style proofs of them in an equational implication calculus. Second, we give a feasible reduction from the equational theory of KAT to the equational theory of KA. Combined with the fact that the Hoare theory of KAT reduces efficiently to the equational theory of KAT, this yields an algorithm capable of generating proofs of a large class of statements about programs.

title: Distance Coloring
abstract: Given a graph G=(V,E), a (d,k)-coloring is an assignment of a color from {1, 2, ..., k} to each vertex of V such that any two vertices within distance d of each other are assigned different colors. We determine the complexity of the (d,k)-coloring problem for all d and k, and enumerate some interesting properties of (d,k)-colorable graphs. Our main result is the discovery of a dichotomy between polynomial and NP-hard instances; for fixed d greater than or equal to 2, the distance coloring problem is polynomial time for k less than or equal to 3d/2 and NP-hard for k greater than 3d/2.

title: EM-Style Geo-Cuts Segmentation for MRI Brain Images
abstract: Segmentation of MRI brain images has great clinical and academic importance. The overlap of MR intensities of different tissue types and the vast amount of thin structures in brain images make segmentation of MRI brain images difficult. In this paper, we present an EM-style geo-cuts-based segmentation method to over come these challenges. We classify the brain images into three tissue types: white matter, gray matter, and CSF. We iteratively classify the voxels and calculate the intensity profile. We use region bias and automatic seed setting combined with intensity profile induced Riemannian metrics for the classification of voxels. We then use this classification to re-estimate the intensity profile. Experimentally, our method gives very good performance on both synthetic images with ground truth segmentation and real images with the segmentation of white matter and CSF improved over the widely used EMS method.

title: Quantifying Information Flow with Beliefs
abstract: To reason about information flow, a new model is developed that describes how attacker beliefs change due to the attacker's observation of the execution of a probabilistic (or deterministic) program. The model enables compositional reasoning about information flow from attacks involving sequences of interactions. The model also supports a new metric for quantitative information flow that measures accuracy of an attacker's beliefs. Applying this new metric reveals inadequacies of traditional information flow metrics, which are based on reduction of uncertainty. However, the new metric is sufficiently general that it can be instantiated to measure either accuracy or uncertainty. The new metric can also be used to reason about misinformation; deterministic programs are shown to be incapable of producing misinformation. Additionally, programs in which nondeterministic choices are made by insiders, who collude with attackers, can be analyzed.

title: Efficient Keyword Search over Virtual XML Views
abstract: Emerging applications such as personalized portals, enterprise search and web integration systems often require keyword search over semi-structured views. However, traditional information retrieval techniques are likely to be expensive in this context because they rely on the assumption that the set of documents being searched is materialized. In this paper, we present a system architecture and algorithm that can efficiently evaluate keyword search queries over virtual (unmaterialized) XML views. An interesting aspect of our approach is that it exploits indices present on the base data and thereby avoids materializing large parts of the view that are not relevant to the query results. Another feature of the algorithm is that by solely using indices, we can still score the results for queries over the virtual view, and the resulting scores and rank order are the same as if the view was materialized. Our performance evaluation using the INEX data set in the Quark open-source XML database system indicates that the proposed approach is scalable and efficient.

title: Secure web applications via automatic partitioning
abstract: Web applications are now critical infrastructure. To improve the user interface, some application functionality is typically implemented as client-side JavaScript code. Currently there are no good methods for deciding when it is secure to move code and data to the client side. Swift is a new, principled approach to building web applications that are secure by construction. Application code is written as Java-like code annotated with information flow policies. This code is automatically partitioned between JavaScript code running in the browser, and Java code running on the server. Code and data are placed on the client side where possible. Security-critical code is placed on the server and user interface code is placed on the client. Code placement is constrained by high-level, declarative information flow policies that strongly enforce the confidentiality and integrity of server-side information. Web applications are hard to build because code and data needs to be partitioned to make them responsive. They are also hard to build because code and data need to be partitioned for security. Because of the connection (and tension) between the two problems, Swift addresses both at once, automatically partitioning application code while also providing assurance that the resulting placement is secure and efficient.

title: Transnational Webs: Overseas Chinese Economic and Political Networks in Colonial Vietnam, 1870-1945
abstract: This dissertation is a study in ethnicity and transnational networks with the primary focus on the Chinese in Indochina, including Cochinchina, Cambodia, and Tonkin, which were under French colonial rule. It is the product of research undertaken at Hanoi's Vietnamese National Archives #1, the Vietnamese National Library in Hanoi, Saigon's Vietnamese National Archives #2, the Centre des Archives d'Outre-Mer in Aix-en-Provence, London's Public Record Office, and the Australian National Library and National Archives in Canberra. Access to these archives has allowed me to place overseas Chinese networks within the contexts of both Chinese and Southeast Asian history. As a result, this work has theoretical implications for transnational studies of borders inside and outside of Asia.
This dissertation is the first transregional study of institutions organized by the overseas Chinese population of Indochina during the French period. These Chinese formed their original organizations in China, and then reached across the China-Indochina border, expanding across Indochina. In China, native-place ties inherited from their fathers bound them together, and after they reached Indochina, they established bases, most often in Saigon-Cholon, and then expanded into other cities and towns where their networks competed for commercial gain and political influence. Narratives of the lives, crimes, and political and economic ventures of scores of overseas Chinese living and working in Cochinchina, Tonkin, and Cambodia provide the backbone for my arguments. At the time, all of these places were under French colonial rule, and Chinese networks negotiated the pathways and pitfalls of French colonial law to achieve their own agendas and maintain multidirectional ties, not only with all of their branches in Indochina but with their native places in China as well. By concentrating on the points where Chinese, Vietnamese, and French interests intersected, I show how they cooperated and came into conflict with each other. Ultimately, I conclude that even while the French held official authority in the colonies of Indochina, Chinese transnational networks exercised unofficial control over decision-making, not only in commerce but also in the wider arenas of politics, law, and society as they pertained to local Chinese communities.

title: Geologic and Strategic Comments on Oil Resources in the Arabian Gulf Region
abstract: This audio recording is in Arabic.Peak oil production in the Middle East's Arabian/Persian Gulf region and worldwide could be delayed if major multinational and national oil companies would invest more heavily in drilling and extraction technologies and push to explore new sites.
Barazangi argued that the "exploration story" in the Middle East is not yet complete. Two-thirds of the world's proven recoverable oil reserves exist in the Arabian Gulf, and there are more oil fields to be discovered through offshore and deep-water drilling, as well as more oil to be extracted from existing fields.
Barazangi stressed the fact that only seven countries worldwide (Saudi Arabia, Iran, Iraq, Kuwait, United Arab Emirates, Venezuela, and Russia) contain 80 percent of the world's proven recoverable oil reserves. Five of those are notably in the Arabian Gulf region and share Islamic cultures. He argued that in order to better understand oil issues in the Gulf, the world must understand the Arab and Persian people, and Islam's history and culture.

title: Rationalizing Responsibility: Weber's Theory of Rationality and the Corporate Social Responsibility Debate
abstract: The corporate social responsibility (CSR) debate arose out of the recognition that corporations today hold tremendous power, and that the direct and indirect implications of their actions are far-reaching, affecting a wide array of stakeholders in both positive and negative ways. Corporate decision-makers are confronted daily with a complex set of often conflicting demands, including economic, ethical, legal, personal and professional demands. They are forced to weigh these competing demands in their decision-making processes, ultimately deciding which demands will influence their corporations? actions. Understanding the rationality employed by corporate decision-makers and business scholars is important in the study of CSR because it allows us to gain insight into how they interpret the constellation of demands placed upon them and how they orient their actions ? and their corporations? actions ? accordingly. I approach this analysis of the CSR discourse with two primary research questions. First, what patterns exist in the arguments put forth in the CSR literature, and can these patterns be classified into theoretical categories of CSR? Second, what rationalities underlie the predominant arguments (theories) in the CSR literature, and how do these rationalities inform the CSR debate? Upon coding the CSR literature according to four points of paradigmatic contention between adherents to different arguments for or against CSR, three endogenous theoretical frameworks began to emerge: corporate libertarian theory, enlightened self-interest theory, and moral theory. While most critics and advocates of CSR in the mainstream discourse point to one or more of the dozens of empirical studies on the CSR-firm financial performance relationship to support their arguments, I suggest that many of the arguments put forth in the CSR discourse are not predicated on empirical evidence, but rather on an underlying normative orientation and rationality. Through this qualitative analysis of the CSR discourse ? both the academic and nonacademic discourse ? the conflicting rationalities employed by participants in the CSR discourse become apparent. In the face of economic globalization, characterized by transnational capital flows, highly mobile corporations, and increasing power of corporations in relation to the state, corporations have become some of the most powerful actors in the world today. Despite the fact that their agency is constrained by the demands of the market system, their actions greatly affect our lives, our world, and our future. The need for a moral discourse on the role and responsibilities of business corporations in society today is pressing. In addition to seeking to understand the rationalities underpinning the predominant arguments for and against CSR, this research seeks to contribute to this growing moral discourse.

title: Influence of fatty acids and sugars released by germinating seeds on plant species specific control of Pythium ultimum by Enterobacter cloacae
abstract: Pythium ultimum is a devastating pathogen of seeds and seedlings. Germination of pathogen sporangia can be elicited by unsaturated long chain fatty acids that are released by germinating seeds. Sporangial activation and germination are critical for initiating Pythium disease development. Pythium infection can be prevented by applying the bacterium Enterobacter cloacae onto seeds and expression of bacterial fatty acid transport and degradation have been found to be important traits for this control. However, the bacterium is capable of protecting only certain seeds such as cotton and cucumber whereas other seeds, such as corn and pea succumb to Pythium infection. It has been postulated that differences in sugar released by seeds may explain this differential protection since sugars are able to repress fatty acid metabolism in E. cloacae. Corn and pea seeds are documented as seeds that release high amounts of simple sugars that can repress fatty acid uptake and catabolism. Experiments focused on the temporal release of corn and cucumber

seed exudates and their induction of sporangial activation, germination, host colonization and the impact E. cloacae had on these pathogen responses while concomitant release of exudate sugars and fatty acids was also analyzed. E. cloacae is able to interrupt sporangial activation induced by cucumber seeds, but not in the corn spermosphere. This explains the differential control by the bacterium, since activation interference directly resulted in suppressed seed colonization. Both corn and cucumber seeds released unsaturated fatty acids as early as 15 min after sowing although quantities from corn exceeded that of cucumber. More importantly, corn seeds released much higher concentrations of simple sugars than cucumber already within 15 min. Quantities detected in corn seed exudate are large enough to completely shut down fatty acid degradation of E. cloacae. This provided the first evidence that interference with sporangial activation is the cause for plant protection by E. cloacae and seeds not protected by E. cloacae are incapable of interfering with sporangial activation. The bacterium does not interfere with sporangial activation because non protected seeds release sugars at such quantities that bacterial fatty acid degradation is repressed.

title: Typed Memory Management in a Calculus of Capabilities
abstract: Region-based memory management is an alternative to standard tracing garbage collection that makes potentially dangerous operations such as memory deallocation explicit but verifiably safe. In this article, we present a new compiler intermediate language, called the Capability Calculus, that supports region-based memory management and enjoys a provably safe type system. Unlike previous region-based type systems, region lifetimes need not be lexically scoped and yet the language may be checked for safety without complex analyses. Therefore, our type system may be deployed in settings such as extensible operating systems where both the performance and safety of untrusted code is important. The central novelty of the language is the use of static capabilities to specify the permissibility of various operations, such as memory access and deallocation. In order to ensure capabilities are relinquished properly, the type system tracks aliasing information using a form of bounded quantification. Moreover, unlike previous work on region-based type systems, the proof of soundness of our type system is relatively simple, employing only standard syntactic techniques. In order to show our language may be used in practice, we show how to translate a variant of Tofte and Talpin's high-level type-and-effects system for region-based memory management into our language. When combined with known region inference algorithms, this translation provides a way to compile source-level languages to the Capability Calculus.

title: Fractal Symbolic Analysis for Program Transformations (*new file*)
abstract: Restructuring compilers use dependence analysis to prove that the meaning of a program is not changed by a transformation. A well-known limitation of dependence analysis is that it examines only the memory locations read and written by a statement, and does not assume any particular interpretation for the operations in that statement. Exploiting the semantics of these operations enables a wider set of transformations to be used, and is critical for optimizing important codes such as LU factorization with pivoting. Symbolic execution of programs enables the exploitation of such semantic properties, but it is intractable for all but the simplest programs. In this paper, we propose a new form of symbolic analysis for use in restructuring compilers. Fractal symbolic analysis compares a program and its transformed version by repeatedly simplifying these programs until symbolic analysis becomes tractable, ensuring that equality

of simplified programs is sufficient to guarantee equality of the original programs. We present a prototype implementation of fractal symbolic analysis, and show how it can be used to optimize the cache performance of LU factorization with pivoting.

title: Tiling Imperfectly-nested Loop Nests (REVISED)
abstract: Tiling is one of the more important transformations for enhancing locality of reference in programs. Tiling of perfectly-nested loop nests (which are loop nests in which all assignment statements are contained in the innermost loop) is well understood. In practice, most loop nests are imperfectly-nested, so existing compilers heuristically try to find a sequence of transformations that convert such loop nests into perfectly-nested ones but not always succeed. In this paper, we propose a novel approach to tiling imperfectly-nested loop nests. The key idea is to embed the iteration space of every statement in the imperfectly-nested loop nest into a special space called the product space. The set of possible embeddings is constrained so that the resulting product space can be legally tiled. From this set we choose embeddings that enhance data reuse. We evaluate the effectiveness of this approach for dense numerical linear algebra benchmarks, relaxation codes, and the tomcatv code from the SPEC benchmarks. No other single approach in the literature can tile all these codes automatically.

title: Scalable Certification of Native Code: Experience from Compiling toTALx86
abstract: Certifying compilation allows a compiler to produce annotations that prove that target code abides by a specified safety policy. An independent verifier can check the code without needing to trust the compiler. For such a system to be generally useful, the safety policy should be expressive enough to allow different compilers to effectively produce certifiable code. In this work, we use our experience in writing a certifying compiler to suggest general design principles that should allow concise yet expressive certificates. As an extended example, we present our compiler's translation of the control flow of Popcorn, a high-level language with function pointers and exception handlers, to TALx86, a typed assembly language with registers, a stack, memory, and code blocks. This example motivates techniques for controlling certificate size and verification time. We quantify the effectiveness of techniques for reducing the overhead of certifying compilation by measuring the effects their use has on a real Popcorn application, the compiler itself. The selective use of these techniques, which include common-subexpression elimination of types, higher-order type abbreviations, and selective re-verification, can change certificate size and verification time by well over an order of magnitude. We consider this report to be the first quantitative study on the practicality of certifying a real program using a type system not specifically designed for the compiler or source language.

title: IRM Enforcement of Java Stack Inspection
abstract: Two implementations are given for Java's stack-inspection access-control policy. Each implementation is obtained by generating an inlined reference monitor (IRM) for a different formulation of the policy. Performance of the implementations is evaluated, and one is found to be competitive with Java's less-flexible, JVM-resident implementation. The exercise illustrates the power of the IRM approach for enforcing security policies.

title: Alias Types for Recursive Data Structures (Extended Version)
abstract: Linear type systems permit programmers to deallocate or explicitly recycle memory, but they are severly restricted by the fact that they admit no aliasing. This paper describes a pseudo-linear type system that allows a degree of aliasing and memory reuse as well as the ability to define complex recursive data structures. Our type system can encode conventional linear data structures such as linear lists and trees as well as more sophisticated data structures including cyclic and doubly-linked lists and trees. In the latter cases, our type system is expressive enough to represent pointer aliasing and yet safely permit destructive operations such as object deallocation. We demonstrate the flexibility of our type system by encoding two common compiler optimizations: destination-passing style and Deutsch-Schorr-Waite or ``link-reversal''

traversal algorithms.

title: Compiling Imperfectly-nested Sparse Matrix Codes with Dependences
abstract: We present compiler technology for generating sparse matrix code from (i) dense matrix code and (ii) a description of the indexing structure of the sparse matrices. This technology embeds statement instances into a Cartesian product of statement iteration and data spaces, and produces efficient sparse code by identifying common enumerations for multiple references to sparse matrices. This approach works for imperfectly-nested codes with dependences, and produces sparse code competitive with hand-written library code.

title: A Decision-Theoretic Approach to Resource Allocation in WirelessMultimedia Networks
abstract: The allocation of scarce spectral resources to support as many user applications as possible while maintaining reasonable quality of service is a fundamental problem in wireless communication. We argue that the problem is best formulated in terms of decision theory. We propose a scheme that takes decision-theoretic concerns (like preferences) into account and discuss the difficulties and subtleties involved in applying standard techniques from the theory of Markov Decision Processes (MDPs) in constructing an algorithm that is decision-theoretically optimal. As an example of the proposed framework, we construct such an algorithm under some simplifying assumptions. Additionally, we present analysis and simulation results that show that our algorithm meets its design goals. Finally, we investigate how far from optimal one well-known heuristic is. The main contribution of our results is in providing insight and guidance for the design of near-optimal admission-control policies.

title: Query Processing with Heterogeneous Resources
abstract: In emerging systems, CPUs and memory are integrated into active disks, controllers, and network interconnects. Query processing on these new multiprocessor systems must consider the heterogeneity of resources among the components. This leads to the more general problem of how to deal with performance heterogeneity in parallel database systems. We study database query processing techniques that increase the leverage of heterogeneous resources. We show that the traditional algorithms used in shared-nothing parallel databases fail to utilize non-uniform resources. Uniform resource usage across non-uniform components leads to resource bottlenecks. We describe a class of new execution techniques that balance the usage of system resources using non-uniform intra-operator parallelism. We show that these techniques improve performance on heterogeneous architectures by allowing trade-offs between the various resources. Traditional techniques are subsumed as a special case for symmetric architectures. We show a formal model that maps out the new execution space of alternative processing techniques. A simplified cost model allows analytic performance evaluation of the alternative techniques. The proposed new execution paradigm is an extension of the classical dataflow paradigm.

title: Agent Technology Applied to Adaptive Relay Setting for Multi-TerminalLines
abstract: Abstract: This paper discusses the adaptation of the settings of distance relays for multi-terminal lines employing agents. Agents are software processes capable of searching for information in networks, interacting with pieces of equipment and performing tasks on behalf of their owners (relays). Results illustrating the performance of the adaptive method proposed compared to conventional fixed settings are presented. It is shown that the digital relays and agents acting within a communication structure (also called middleware) can alter adaptive settings to ensure correct performance over a wide variety of operation conditions, without the need of an additional communication link. The proposed relaying scheme can also be utilized for first zone clearing over the entire line.

title: A Probabilistically Correct Leader Election Protocol for Large Groups
abstract: This paper presents a scalable leader election protocol for large process groups with a weak membership requirement. The underlying network is assumed to be unreliable but characterized by probabilistic failure rates of processes and message deliveries. The protocol trades correctness for scale, that is, it provides very good probabilistic guarantees on correct termination in the sense of the classical specification of the election problem, and of generating a constant number of messages, both independent of group size. After formally specifying the probabilistic properties, we describe the protocol in detail. Our subsequent mathematical analysis provides probabilistic bounds on the complexity of the protocol. Finally, the results of simulation show that the performance of the protocol is satisfactory.

title: Set Reconciliation with Nearly Optimal Communication Complexity
abstract: We consider a fundamental problem that arises in the context of gossip protocols. Specifically, we consider the problem of efficiently reconciling two similar sets held by different hosts while minimizing the communication complexity. We provide two surprisingly simple and efficient protocols that exhibit tractable computational complexity and nearly optimal communication complexity. These protocols can be adapted to work over a broadcast channel, allowing many clients to reconcile with one host based on a broadcasted signal.\note{We keep on bouncing back and forth on whether the ``a"s are necessary. I like it better without, but it's not a big deal.} Thus, an arbitrary number of clients each of whose data differs from that of the host by no more than N bits can be reconciled by a single broadcast of $O(N)$ bits, independent of the the number of clients and independent of the size of the data sets.

title: Speeding Up Short Data Transfers: Theory, Architectural Support, andSimulation Results
abstract: Today's Internet traffic is dominated by short Web data transfers. Such a workload is well known to interact poorly with the TCP protocol. TCP uses the slow start procedure to probe the network for bandwidth both at connection start up and upon restart after an idle period. This usually requires several roundtrips and is inefficient when the duration of a transfer is short. In this paper, we propose a new technique, which we call TCP/SPAND, to speed up short data transfers. In TCP/SPAND, network performance information is shared among many co-located hosts to estimate each connection's fair share of the network resources. Based on such estimation and the transfer size, the TCP sender determines the optimal initial congestion window size. Instead of doing slow start, it uses a pacing scheme to smoothly send out the packets in its initial congestion window. We use extensive simulations to evaluate the performance of the resulting system. Our results show that TCP/SPAND significantly reduces latency for short transfers even in presence of multiple heavily congested bottlenecks. Meanwhile, the performance benefit does not come at the expense of degrading the performance of connections using the standard TCP. That is, TCP/SPAND is TCP friendly.

title: Accommodating Simplicity and Complexity in Metadata: Lessons from theDublin Core Experience
abstract: The Dublin Core Metadata Element Set (DCMES) grew out of a recognized need for improved resource discovery of web resources. Initial work on the DCMES focused on the requirement of simplicity: "ordinary" users should be able to formulate descriptive records based on a relatively simple schema (fifteen free-text elements). Over the years there has been a movement within the Dublin Core community to use the DCMES for more complex and specialized resource description tasks and, correspondingly, develop mechanisms for incorporating such complexity within the basic element set. This work has generally been called qualified Dublin Core. We examine the notion of accommodating complexity in a simple metadata model and argue that the dual requirements are incompatible. We discuss the role of events and processes in more expressive metadata and how simple resource-centric models, such as DCMES, are not equipped to express these semantics

title: A Graph Based Algorithm for Bayesian Object Recognition
abstract: We introduce an approach to feature-based object recognition, using maximum a posteriori (MAP) estimation under a Markov random field (MRF) model. Our approach assumes that both the location of the model and a configuration of matching features are not directly observable and have to be estimated. We consider a wide class of priors that explicitly model dependencies between individual features of an object. These priors capture phenomena such as the fact that unmatched features due to partial occlusion are generally

spatially correlated rather than independent. Our algorithm uses an efficient graph cut technique to resolve technical difficulties introduced by dependencies between the features. The method allows hierarchical search space pruning to find the location of the model. A special case of our framework yields a particularly efficient approximation method. We call this special case {\em spatially coherent matching} (SCM). The SCM method operates directly on the image feature map, rather than relying on the graph-based methods used in the general framework. Interestingly, in the extreme case of completely independent features our general Bayesian framework reduces to Hausdorff matching. We present some Monte Carlo experiments showing that models accounting for dependencies between the features can yield substantial improvements over Hausdorff matching for cluttered scenes and partially occluded objects.

title: Fast Firewall Implementations for Software-based Routers
abstract: Routers must perform packet classification at high speeds to efficiently implement functions such as firewalls. The classification can be based on an arbitrary number of prefix and range fields in the packet header. The classification required for firewalls is beyond the capabilities offered by standard Operating System classifiers such as BPF~\cite{MJ93}, DPF~\cite{EK96}, PathFinder~\cite{BGS94} and others. In fact, there are theoretical results that show the general firewall lassification problem has poor worst case cost: for searching over N arbitrary filters using k packet fields, either the worst-case search time is $\Omega((\log N)^{k-1})$ or the worst-case storage is $O(N^{k})$. In this paper, we re-examine two basic mechanisms that have been dismissed in the literature as being too inefficient: backtracking search and set pruning trees. We find using real databases that the time for backtracking search is much better than the worst case bound; instead of $\Omega((logN)^{k-1})$, the search time is only roughly twice the optimal search time\footnote{\scriptsize The height of the multiplane trie is regarded as optimal search time throughout the paper, unless otherwise specified.}. Similarly, we find that set pruning trees (using a DAG optimization) have much better storage costs than the worst case bound; it has memory requirements similar to the RFC scheme of Gupta and McKeown~\cite{GM99}. We also propose several new techniques to further improve the two basic mechanisms. Our major ideas are a novel compression algorithm, the ability to trade smoothly between backtracking and set pruning, and algorithms to effectively make use of hardware if hardware is available. We quantify the performance gain of each technique using real databases. We show that on real firewall databases our schemes, with the accompanying optimizations, are close to optimal in time and storage.

title: On the Placement of Web Server Replicas
abstract: Recently there has been an increasing deployment of content distribution networks (CDNs) that offer hosting services to Web content providers. CDNs deploy a set of servers distributed throughout the Internet and replicate provider content across these servers for better performance and availability than centralized provider servers. Existing work on CDNs has primarily focused on techniques for efficiently redirecting user requests to appropriate CDN servers to reduce request latency an d balance load. However, little attention has been given to the development of placement strategies for Web server replicas to further improve CDN performance. In this paper, we explore the problem of Web server replica placement in detail. We develop several placement algorithms that use workload information, such as client latency and request rates, to make informed placement decisions. We then evaluate the placement algorithms using both synthetic and

real network topologies, and real Web server traces, and show that the placement of Web replicas is crucial to CDN performance. We also address a number of practical issues when using these algorithms, such as their sensitivity to imperfect knowledge about client workload and network topology, the stability of the input data, methods for obtaining the input, and the scalability of the algorithms.

title: Modeling Decisions for Digital Content
abstract: The organization of digital information poses unique challenges not only due to rapidly evolving data formats and software, but also because digital content may be dynamic, distributed, or executable. Managers of digital information need flexible, extensible architectures that facilitate maintainability as well as accessibility and long-term utility of content. However, the flexibility of these architectures presents difficult organizational, or modeling, decisions. To explore these modeling decisions and their consequences, we introduce four dimensions of digital content modeling: aggregation, interfaces, transformations and indirection. We discuss these dimensions individually and also examine their interaction; in essence, this paper examines general design patterns for digital content modeling. As new and powerful architecture evolve, it is vital that information mangers understand and consider these design decisions.

title: The Bernoulli Generic Matrix Library
abstract: We have implemented the Bernoulli generic programming system for sparse matrix computations. What distinguishes it from existing generic sparse matrix libraries is that we use (i) a high-level matrix abstraction for writing generic matrix programs, (ii) a low-level matrix abstraction for describing the indexing structure and properties of sparse matrices formats, and (iii) restructuring compiler technology to transform the high-level generic programs into concrete implementations that efficiently access sparse matrices using the low-level abstraction. This paper describes the Bernoulli Generic Matrix Library (BGML). The BGML is the C++ implementation of these high-level and low-level abstractions. Within our system, it serves as the ``glue'' between user's sparse matrix format implementations and the restructuring sparse compiler. In this paper, we present the interfaces of the BGML and give examples of their use. Because of its role, it is critical that the BGML not impose much of an overhead on the compiler generated code. We discuss the implementation techniques that we had to use to get the most performance from the BGML. We also discuss the difficulties that we encountered in using available C++ compilers on the BGML.

title: Confidentiality and Integrity with Untrusted Hosts: Technical Report
abstract: Several security-typed languages have recently been proposed to enforce security properties such as confidentiality or integrity by type checking. We propose a new security-typed language, SPL@, that addresses two important limitations of previous approaches. First, existing languages assume that the underlying execution platform is trusted; this assumption does not scale to distributed computation in which a variety of differently trusted hosts are available to execute programs. Our new approach, secure program partitioning, translates programs written assuming complete trust in a single executing host into programs that execute using a collection of variously trusted hosts to perform computation. As the trust configuration of a distributed system evolves, this translation can be performed as necessary for security. Second, many common program transformations do not work in existing security-typed languages; although they produce equivalent programs, these programs are rejected because of apparent information flows. SPL@ uses a novel mechanism based on ordered linear continuations to permit a richer class of program transformations, including secure program partitioning. This report is the technical companion to [ZM00]. It contains expanded discussion and extensive proofs of both the soundness and noninterference theorems mentioned in Section 3.3 of that work.

title: Locality Enhancement Of Imperfectly-nested Loop Nests
abstract: Most numerical applications using arrays require extensive program transformation in order to perform well on current machine architectures with deep memory hierarchies. These transformations ensure that an execution of the application exploits data-locality and uses the caches more effectively. The problem of exploiting data-locality is well understood only for a small class of applications -- for programs in which all statements are present in the innermost loop of a loop-nest (called perfectly-nested loops). For such programs, statement instances can be mapped to an integer lattice (called the iteration space), and important transformations can be modelled as unimodular transformations of the iteration space. This framework has permitted the systematic application of transformations like loop-permutation, skewing and tiling in order to enhance locality in perfectly-nested loops. In dealing with programs that do not fall into this category, current compilers resort to ad-hoc techniques to find the right sequence of transformations. For some important benchmarks, no technique is known that will discover the right sequence of transformations. In my thesis, I propose a technique that extends the framework for perfectly-nested loops to general programs. The key idea is to embed the iteration space of every statement in the program into a special iteration space called the product space. The product space can be viewed as a perfectly-nested loop nest, so this embedding generalizes techniques like code sinking and loop fusion that are used in ad hoc ways in current compilers to produce perfectly-nested loops from imperfectly-nested ones. In contrast to these ad hoc techniques however, embeddings are chosen carefully to enhance locality. The product space is then transformed further using unimodular transformations, after which fully permutable loops are tiled, and code is generated. Code can also be generated to emulate block-recursive versions of the original program. I demonstrate the effectiveness of this approach for dense numerical linear algebra benchmarks, relaxation codes, and the tomcatv code from the SPECfp95 benchmark suite.

title: Tactic-Based Modeling of Cognitive Inference on Logically StructuredNotation
abstract: Computational (algorithmic) models of high-level cognitive inference tasks such as logical inference, mathematical inference, and decision making can have both theoretical and practical impact. They can improve our theoretical understanding of how people think and also provide practical direction for applications such as automated reasoning systems, systems attuned to user-interaction in decision-critical environments, and computer-aided education. To support those benefits, cognitive models need to be detailed, compositional, based in well-understood mathematics, and, to whatever extent possible, descriptively accurate. We introduce a new, interdisciplinary approach that could be used to develop cognitive models of high-level inference with these properties. Two significant aspects of this approach are tactics and eyetracking methods. Tactics are used to express high-level inferences in fully formalized mathematics for automated theorem proving systems; eyetracking methods provide insight into real-time and microcognitive information processing by permitting analysis of the visual attention of people performing cognitive tasks. Combining tactics and eyetracking methods with traditional techniques from applied logic, artificial intelligence, and cognitive science can result in more deeply detailed and accurate cognitive models. We demonstrate the feasibility of this new approach to modeling by describing its application to a calculational logic system that supports schematic reasoning via metalinguistic operations (such as textual substitution) without resorting to higher-order logic. We discuss several computational, psychological, and pedagogical insights that resulted from this approach, and we present a detailed, tactic-based model of calculational logic inference. Specific results include: an explanation of calculational logic as a formalized metalogic; a tactic-based implementation of calculational logic inference; some pedagogical observations on the teaching of calculational logic; and experimental results that demonstrate that eyetracking methods can provide insight into theorem proving that could not be achieved by studies of written work alone.

title: Set Reconciliation with Nearly Optimal Communication Complexity
abstract: We consider the problem of efficiently reconciling two similar sets held by different hosts while minimizing the communication complexity. This type of problem arises naturally from gossip protocols used for the distribution of information. We describe an aproach to set reconciliation based on the encoding of sets as polynomials. The resulting protocols exhibit tractable computational complexity and nearly optimal communication complexity. Also, these protocols can be adapted to work over a broadcast channel, allowing many clients to reconcile with one host based on a single broadcast, even if each client is missing a different subset.

title: A Randomized Error Recovery Algorithm for Reliable Multicast
abstract: An efficient error recovery algorithm is essential for reliable multicast in large groups. Tree-based protocols (RMTP, TMTP, LBRRM) group receivers into local regions and select a repair server for performing error recovery in each region. Hence a single server bears the entire responsibility of error

recovery for a region. In addition, the deployment of repair servers requires topological information of the underlying multicast tree, which is generally not available at the transport layer. This paper presents RRMP, a randomized reliable multicast protocol which improves the robustness of tree-based protocols by diffusing the responsibility of error recovery among all members in a group. The protocol works well within the existing IP multicast framework and does not require additional support from routers. Both analysis and simulation results show that the performance penalty due to randomization is low and can be tuned according to application requirements.

title: Optimizing Buffer Management for Reliable Multicast
abstract: Reliable multicast delivery requires that a multicast message be received by all members in a group. Hence certain or all members need to buffer messages for possible retransmissions. Designing an efficient buffer management algorithm is challenging in large multicast groups where no member has complete group membership information and the delivery latency to different members could differ by orders of magnitude. We propose an innovative two-phase buffering algorithm, which explicitly addresses variations in delivery latency seen in large multicast groups. The algorithm effectively reduces buffer requirements by adaptively allocating buffer space to messages most needed in the system and by spreading the load of buffering among all members in the group. Simulation results demonstrate that the algorithm has good performance.

title: IP Paging Service for Mobile Hosts
abstract: In wireless networks, mobile hosts must update the network with their current location in order to get packets delivered to them. Paging facilitates efficient power management at the mobile host by allowing the host to update the network less frequently at the cost of providing the network with only approximate location information. The network determines the exact location of a mobile host through paging before delivering packets destined to the mobile host. In current circuit-switched wireless networks, paging is implemented as a special purpose functionality in a centralized component inside the network. Given the emergence of different packet-switched wireless networks, we propose a novel router service called IP paging. This enables one common IP-based infrastructure to support different wireless interfaces such as CDMA, GPRS, Wireless LAN, etc. In this paper, we present the design, implementation, and detailed performance evaluation, using measurements and simulation, of three IP-based paging protocols for mobile hosts.

title: Automatic Extraction of Reference Linking Information from OnlineDocuments
abstract: The Web, with its explosive growth, is becoming an efficient resource for up-to-date information for the scientific researcher. Informal online archives are repositories for technical reports. Proceedings are more and more commonly published on the Web. The collection of online journals is growing. Indeed, a good number of online journals are "born digital". Many researchers simply put their papers up on their own web site. The large volume of online material makes it quite desirable to be able to access cited documents immediately from the citing paper. Implementing this direct access is called "reference linking". Some reference linking services exist today. A number of commercial publishers, recognizing the significant value-added nature of reference linking, have banded together to form the CrossRef organization. The CrossRef publishers share their metadata, which enables them to interlink their journals. This metadata is not, however, available without a fee to organizations or individuals outside of CrossRef. The vast majority of online scholarly literature is accompanied by little or no metadata. Since it is desirable to link up this literature as well, the problem of automatically reference linking online scholarly literature in the absence of metadata and author intervention is a problem very much worth considering. This paper explores this problem in detail, and presents some algorithms for extracting metadata from online texts and linking full-text documents together. The extent to which reference linking of the online literature can be done automatically is therefore the main topic of this paper.

title: The Architecture and Performance of Security Protocols in the EnsembleGroup Communication System
abstract: Ensemble is a Group Communication System built at Cornell and the Hebrew universities. It allows processes to create process groups within which scalable reliable fifo-ordered multicast and point-to-point communication are supported. The system also supports other communication properties, such as causal and total multicast ordering, flow control, etc. This paper describes the security protocols and infrastructure of Ensemble. Applications using Ensemble with the extensions described here benefit from strong security properties. Under the assumption that trusted processes will not be corrupted, all communication is secured from tampering by outsiders. Our work extends previous work performed in the Horus system (Ensemble's predecessor) by adding support for multiple partitions, efficient rekeying, and application defined security policies. Unlike Horus, which used its own security infrastructure with non-standard key distribution and timing services, Ensemble's security mechanism is based on off-the shelf authentication systems, such as PGP and Kerberos. We extend previous results on group rekeying, with a novel protocol that makes use of diamond-like data structures. Our Diamond protocol allows the removal of untrusted members within milliseconds.

title: Using AVL Trees for Fault Tolerant Group Key Management
abstract: In this paper we describe an efficient algorithm for the management of group-keys for Group Communication Systems. Our algorithm is based on the notion of key-graphs, previously used for managing keys in large IP-multicast groups. The standard protocol requires a centralized key-server that has knowledge of the full key-graph. Our protocol does not delegate this role to any one process. Rather, members enlist in a collaborative effort to create the group key-graph. The key-graph contains n keys, of which each member learns log_2n. We show how to balance the key-graph, a result that is applicable to the centralized protocol. We also show how to optimize our distributed protocol and provide a performance study of its capabilities.

title: Compiling for Runtime Code Generation (Extended Version)
abstract: Cyclone is a programming language that provides explicit support for dynamic specialization based on runtime code generation. To generate specialized code quickly, our Cyclone compiler uses a template based strategy in which pre-compiled code fragments are stitched together at runtime. To achieve good performance, the pre-compiled fragments must be optimized. This paper describes a principled approach to achieving such optimizations. In particular, we generalize standard flow-graph intermediate representations to support templates, define a formal mapping from (a subset of) Cyclone to this representation, and describe a data-flow analysis framework that supports standard optimizations. This extended version contains two mappings to the intermediate representation, a less formal one that emphasizes the novelties of our translation strategy and a purely functional one that is better suited to formal reasoning.

title: Myhill-Nerode Relations on Automatic Systems and the Completeness of Kleene Algebra
abstract: It is well known that finite square matrices over a Kleene algebra again form a Kleene algebra. This is also true for infinite matrices under suitable restrictions. One can use this fact to solve certain infinite systems of inequalities over a Kleene algebra. Automatic systems are a special class of infinite systems that can be viewed as infinite-state automata. Automatic systems can be collapsed using Myhill-Nerode relations in much the same way that finite automata can. The Brzozowski derivative on an algebra of polynomials over a Kleene algebra gives rise to a triangular automatic system that can be solved using these methods. This provides an alternative method for proving the completeness of Kleene algebra.

title: COCA: A Secure Distributed On-line Certification Authority
abstract: COCA is a fault-tolerant and secure on-line certification authority that has been built and deployed both in a local area network and in the Internet. Replication is used to achieve availability; proactive recovery with threshold cryptography is used for digitally signing certificates in a way that defends against mobile adversaries which attack, compromise, and control one replica for a limited period of time before moving on to another. Relatively weak assumptions characterize environments in which COCA's protocols will execute correctly. No assumption is made about execution speed and message delivery delays; channels are expected to exhibit only intermittent reliability; and with 3t+1 COCA servers up to t may be faulty or compromised. The result is a system with inherent defenses to certain denial of service attacks because, by their very nature, weak assumptions are difficult for attackers to invalidate. In addition, traditional techniques, including request authorization, resource management based on segregation and scheduling different classes of requests, as well as caching results of expensive cryptographic operations further reduce COCA's vulnerability to denial of service attacks. Results from experiments in a local area network and the Internet allow a quantitative evaluation of the various means COCA employs to resist denial of service attacks.

title: Efficient Error Recovery For Reliable Multicast
abstract: Multicast is an efficient mechanism for distributing data from one sender to multiple receivers. Many applications need a reliable multicast service which is not provided by the existing IP multicast protocol. Providing such a service on a large scale requires efficient algorithms for error recovery. This dissertation presents a randomized reliable multicast protocol called RRMP which has demonstrably achieved several good properties. The protocol eliminates message implosion by diffusing the responsibility of error recovery among all members in the group and improves the robustness of the system against process failures. It provides good local recovery by dynamically organizing members into an error recovery hierarchy according to their geographic locations. It optimizes buffer management through an innovative two-phase buffering algorithm that explicitly addresses the variances in delivery latency for large multicast groups. The algorithm reduces buffer requirements by adaptively allocating buffer space to messages most needed in the system and by spreading the load of buffering among all members in the group. The key idea of RRMP is to use randomization as a powerful technique to achieve high robustness and efficiency in reliable multicast communications. The RRMP protocol works well within the existing IP multicast framework and does not require additional support from network routers. Both analysis and experimental results show that the performance penalty due to randomization is low and can be tuned according to application requirements.

title: Quotation and Reflection in Nuprl and Scheme
abstract: Relationships between the concepts of proof systems and programming languages are known. Some are well demonstrated in systems like Coq and Nuprl, but other aspects have not been fully implemented, such as reflection. I believe that the true context in which such ideas are becoming useful is when they are implemented, this ``implementation as understanding'' principle is the reason some parts of the following text contain code pieces. This should take the form of a logical environment with reflection mechanisms, Nuprl is a good choice since it is used for connecting logic and programming languages. Therefore, the first step towards creating such an implementation should be taken: pinpointing what should be done, and how. This paper is an attempt to do this.

title: Automata on Guarded Strings and Applications
abstract: Guarded strings are like ordinary strings over a finite alphabet P, except that atoms of the free Boolean algebra on a set of atomic tests B alternate with the symbols of P. The regular sets of guarded strings play the same role in Kleene algebra with tests as the regular sets of ordinary strings do in Kleene algebra. In this paper we develop the elementary theory of finite automata on guarded strings, a generalization of the theory of finite automata on ordinary strings. We give several basic constructions, including determinization, state minimization, and an analog of Kleene's theorem. We then use these results to verify a conjecture on the complexity of a complete Gentzen-style sequent calculus for \partial correctness. We also show that a basic result of the theory of Boolean decision diagrams (BDDs), namely that minimal ordered BDDs are unique,

is a special case of the Myhill-Nerode theorem for a class of automata on guarded strings.

title: Minimal CDMA Recoding Strategies in Power-Controlled Ad-Hoc WirelessNetworks
abstract: The problem of Code Division Multiple Access (CDMA) code assignment to eliminate primary and hidden collisions in multihop packet radio networks has been widely researched in the past. However, very little work has been done on the very realistic *distributed, dynamic* version of the transmitter-oriented code assignment (TOCA) problem in an ad-hoc network where mobiles use CDMA technology. None of the existing dynamic TOCA CDMA algorithms in literature are efficient, in terms of maximum code index assigned in the network, or number of times a mobile has to change its code. We present a set of local and distributed *recoding* strategies for the TOCA CDMA problem in an ad-hoc network where mobiles can arbitrarily 1) connect and disconnect, 2) move about, and 3) increase or decrease their transmission power - all these may need some mobiles to be recoded, to avoid new collisions. Our strategies, unlike those proposed earlier in literature, guarantee *minimal recoding*, that is, given a current network-wide code assignment and one of the above events, our strategies change the codes of the minimum number of mobiles needed to eliminate all collisions. Minimal recoding can be very important in reducing the effect of frequent code changes on the performance and criticality of distributed applications. Further, among all possible minimal recoding strategies in a class, most of our strategies are also (provably) *optimal* in terms of the maximum code index assigned in the network. Performance results that evaluate our dynamic minimal strategies are also presented.

title: Reference Linking the Web's Scholarly Papers
abstract: Along with the explosive growth of the Web has come a great increase in on-line scholarly literature. Thus the Web is becoming an efficient source of up-to-date information for the scientific researcher, and more and more researchers are turning to their computers to keep current on results in their field. Not only is Web retrieval usually faster than a walk to the library, but the information obtained from the Web is potentially more current than what appears in printed publications. The increasing proportion of on-line scholarly literature makes it possible to implement functionality desirable to all researchers -- the ability to access cited documents immediately from the citing paper. Implementing this direct access is called "`reference linking". While many authors insert explicit links into their papers to support reference linking, it is by no means a universal practice. The approach taken by the Digital Library Research Group at Cornell employs "value-added surrogates" to enhance the reference-linking behavior of Web documents. Given the URL of an on-line paper, a surrogate object is constructed for that paper. The surrogate fetches the content of the document and parsesit to automatically extract reference linking data. Applications can then use the surrogate to access this reference linking data, encoded in XML, via a well-defined Java API. We use this API to reference link the D-Lib magazine, an on-line journal of technical papers relating to digital library research. Currently we are (automatically) extractingreference linking information from the papers in this journal with 80% accuracy.

title: Anonymous Gossip: Improving Multicast Reliability in Mobile Ad-HocNetworks
abstract: In recent years, a number of applications of ad-hoc networks have been proposed. Many of them are based on the availability of a robust and reliable multicast protocol. In this paper, we address the issue of reliability and propose a scalable method to improve packet delivery of multicast routing protocols and decrease the variation in the number of packets received by different nodes. The proposed protocol works in two phases. In the first phase, any suitable protocol is used to multicast a message to the group, while in the second concurrent phase, the gossip protocol tries to recover lost messages. Our proposed gossip protocol is called Anonymous Gossip(AG) since nodes need not know the other group members for gossip to be successful. This is extremely desirable for mobile nodes, that have limited resources, and where the knowledge of group membership is difficult to obtain. As a first step, anonymous gossip is implemented over MAODV without much overhead and its performance is studied. Simulations show that the packet delivery of MAODV is significantly improved and the variation in number of packets delivered is decreased.

abstract: Integrating fault tolerance and security is crucial for building trustworthy on-line services. Such integration is studied in this dissertation through the design and implementation of COCA (Cornell On-

line Certification Authority), a fault-tolerant and secure on-line certification authority. COCA maintains a service private key to sign the responses it sends to clients, and achieves availability using replicated servers that employ threshold cryptography and store shares of the service private key. Periodic share refreshing, coupled with periodic recovery of server states, defends against so-called mobile adversaries which move from one server to another. COCA is designed for a weak system model: no assumptions are made about server speed or message delay, and communications are assumed to employ links that are intermittent. The result is a service with reduced vulnerability to attacks because, by their nature, weaker assumptions are more difficult for adversaries to invalidate. COCA further employs an array of defense mechanisms specific to denial of service attacks. COCA runs both on a local area network and on the Internet. Performance measurements of COCA under simulated denial of service attacks demonstrate the effectiveness of COCA's defenses.

title: Toward a Theory of Information Preservation
abstract: Digital preservation is a pressing challenge to the library community. In this paper, we describe the initial results of our efforts towards understanding digital (as well as traditional) preservation problems from first principles. Our approach is to use the language of mathematics to formalize the concepts that are relevant to preservation. Our theory of _preservation spaces_ draws upon ideas from logic and programming language semantics to describe the relationship between concrete objects and their information contents. We also draw on game theory to show how objects change over time as a result of uncontrollable environment effects and directed preservation actions. In the second half of this paper, we show how to use the mathematics of universal algebra as a language for objects whose information content depends on many components. We use this language to describe both migration and emulation strategies for digital preservation.

title: An Architecture for Automatic Reference Linking (Extended Version)
abstract: Along with the explosive growth of the Web has come a great increase in on-line scholarly literature. More and moNot only is Web retrieval usually faster than a walk to the library, but the information obtained from the Web is generally more current than what appears in printed publications. The increasing proportion of on-line scholarly literature makes it possible to implement functionality desirable to all researchers -- the ability to access cited documents immediately from the citing paper. Implementing this direct access is called "reference linking". While many authors insert explicit hyperlinks into their papers to support reference linking, it is by no means a universal practice. The approach taken by the Digital Library Research Group at Cornell employs "value-added surrogates" as a generalizable mechanism for providing reference-linking behavior in Web documents. Given the URL of an on-line document, a surrogate object is constructed for that paper, which then processes document's content to extract reference linking data. The surrogate then exposes the reference linking data through a well-defined API, permitting the construction of reference linking services by external clients. We present two examples of the many possible reference linking applications buildable on this API. We also describe a metric that measures the API's performance; currently we are (automatically) extracting reference linking information from HTML papers with more than 80

title: The Document Representation Problem: An Analysis of LSI and IterativeResidual Rescaling
abstract: Important text analysis problems in information retrieval and natural language processing, such as document clustering and automatic text summarization, require accurate measurement of inter-document similarity. The goal of this work is to find methods for automatically creating document representations in which inter-document similarity measurements correspond to human judgment. We present a new model for the task of creating document representations. From this model, we derive a new analysis of Latent Semantic Indexing (LSI), which is one of the successful approaches that has been studied extensively. In particular, we show a precise relationship between LSI's performance and the uniformity of the underlying distribution of documents over topics. As a consequence, we propose a novel alternative method called Iterative Residual Rescaling (IRR), that, crucially, compensates for distributional non-uniformity. Experiments over a variety of practically-encountered settings and with several evaluation metrics validate our theoretical prediction and confirm the effectiveness of IRR in comparison to LSI. We also propose several extensions including a new document sampling method to scale IRR up to large document collections. Comparison with random sampling provides further empirical evidence that performance can be improved by counteracting non-uniformity. Finally, we present a system for multi-document summarization based on IRR, which demonstrates that IRR can be immediately useful in applications. We show that IRR works as a framework to find a tightly connected (and therefore interpretable) set of coherent texts, and effectively present them to the user.

title: Kleene Algebra with Tests and Program Schematology
abstract: The theory of flowchart schemes has a rich history going back to Ianov (1960); see Manna (1974) for an elementary exposition. A central question in the theory of program schemes is scheme equivalence. Manna presents several examples of equivalence proofs that work by simplifying the schemes using various combinatorial transformation rules. In this paper we present a purely algebraic approach to this problem using Kleene algebra with tests (KAT). Instead of transforming schemes directly using combinatorial graph manipulation, we regard them as a certain kind of automaton on abstract traces. We prove a generalization of Kleene's theorem and use it to construct equivalent expressions in the language of KAT. We can then give a purely equational proof of the equivalence of the resulting expressions. We prove soundness of the method and give a detailed example of its use.

title: Secure Program Partitioning
abstract: This paper presents secure program partitioning, a language-based technique for protecting confidential data during computation in distributed systems containing mutually untrusted hosts. Confidentiality and integrity policies can be expressed by annotating programs with security types that constrain information flow; these programs can then be partitioned automatically to run securely on heterogeneously trusted hosts. The resulting communicating subprograms collectively implement the original program, yet the system as a whole satisfies the security requirements of participating principals without requiring a universally trusted host machine. The experience in applying this methodology and the performance of the resulting distributed code suggest that this is a promising way to obtain secure distributed computation. This Technical Report is an expanded version of the published paper ``Untrusted Hosts and Confidentiality: Secure Program Partitioning.'' The main difference between the two is Appendix A, which contains a correctness proof for the control-transfer protocols described in Section 5.

title: The Price of Anarchy with Polynomial Edge Latency
abstract: We consider the problem of routing traffic to optimize the performance of a congested network. We are given a network, a rate of traffic between each pair of nodes, and a latency function for each edge specifying the time needed to traverse the edge given its congestion; the objective is to route traffic such that the sum of all travel times---the total latency---is minimized. In many settings, it is not possible to implement an optimal assignment of routes. In the absence of regulation by some central authority, we assume that each network user routes its traffic on the minimum-latency path available to it, given the network congestion caused by the other users. In general such a ``selfishly motivated'' assignment of traffic to paths will not minimize the total latency; hence, this lack of regulation carries the cost of decreased network performance. In this paper, we prove that if the latency of each edge is a polynomial function of degree at most p of the edge congestion, then the total latency of the routes chosen by selfish network users is at most $[1 - p \cdot (p+1)^{-(p+1)/p}]^{-1} = \Theta(\frac{p}{\ln p})$ times the minimum possible total latency. A simple example shows that this result is best possible for all values of p.

title: Gossip-Based Ad Hoc Routing
abstract: Many ad hoc routing protocols are based on(some variant of) flooding. Despite various optimizations, many routing messages are propagated unnecessarily. We propose a gossiping-based approach to reduce the overhead of the routing protocols. In large networks, Gossiping exhibits bimodal behavior in sufficiently large networks: in some executions, the gossip dies out quickly and hardly any node gets the message; in the remaining executions, a substantial fraction of the nodes gets the message. The fraction of executions in which most nodes gets the message depends on the gossiping probability and the topology of the network. In the networks we have considered, using gossiping probability between 0.6 and 0.8 suffices to ensure that almost every node gets the message in almost every execution. For large networks, this simple gossiping protocol uses up to 35% fewer messages than flooding, with improved performance. Gossiping can also be combined with various optimizations of flooding to yield further benefits. Simulations show that adding

gossiping to AODV results in significant performance improvement, even in networks as small as 150 nodes only. We expect that the improvement should be even more significant in larger networks.

title: Efficient Computation of Interprocedural Control Dependence
abstract: Control dependence information is useful for a wide range of software maintenance and testing tasks. For example, program slicers use it to determine statements and predicates that might affect the value of a particular variable at a particular program location. In the intraprocedural context an optimal algorithm is known for computing control dependence which unfortunately relies critically on the underlying intraprocedural postdominance relation being tree-structured. Hence, this algorithm is not directly applicable to the interprocedural case where the transitive reduction of the postdominance relation can be a directed acyclic graph (DAG), with nodes having multiple immediate dominators. In this paper we present two efficient, conceptually simple algorithms for computing the interprocedural postdominance relation that can be used to compute interprocedural control dependence. For an interprocedural control flow graph $G=(V,E)$, our reachability based algorithm takes time and space $O(|V|^2 + |V||E|)$. Unlike other algorithms, it does not perform confluence operations on whole bit-vectors and can be tuned to concentrate on the interprocedural rather than intraprocedural relations in a program thus allowing it to scale better to larger programs.

title: Automatic Code Placement Alternatives for Ad-Hoc And Sensor Networks
abstract: Developing applications for ad-hoc and sensor networks poses significant challenges. Many interesting applications in these domains entail collaboration between components distributed throughout an ad-hoc network. Defining these components, optimally placing them on nodes in the ad-hoc network and relocating them in response to changes is a fundamental problem faced by such applications. Manual approaches to code and data migration are not only platform-dependent and error-prone, but also needlessly complicate application development. Further, locally optimal decisions made by applications that share the same network can lead to globally unstable and energy inefficient behavior. In this paper we describe the design and implementation of a distributed operating system for ad-hoc and sensor networks whose goal is to enable power-aware, adaptive, and easy-to-develop ad-hoc networking applications. Our system achieves this goal by providing a single system image of a unified Java virtual machine to applications over an ad-hoc collection of heterogeneous nodes. It automatically and transparently partitions applications into components and dynamically finds a placement of these components on nodes within the ad-hoc network to reduce energy consumption and increase system longevity. This paper outlines the design of our system and evaluates two practical, power-aware, online algorithms for object placement that form the core of our system. We demonstrate that our algorithms can increase system longevity by a factor of four to five by effectively distributing energy consumption, and are suitable for use in an energy efficient operating system in which applications are distributed automatically and transparently.

title: Tolerating Malicious Gossip
abstract: A new class of gossip protocols is presented to diffuse updates securely. The protocols rely on annotating updates with the path along which they travel. To avoid a combinatorial explosion in the number of such annotated updates, rules are employed to choose which updates to keep. Different sets of rules lead to different protocols. Results of simulated executions of a collection of such protocols are described---the protocols would appear to be practical, even in large networks.

title: Formal Type Soundness for Cyclone's Region System
abstract: Cyclone is a polymorphic, type-safe programming language derived from C\@. The primary design goals of Cyclone are to let programmers control data representations and memory management without sacrificing type-safety. In this paper, we focus on the region-based memory management of Cyclone and its static typing discipline. The design incorporates several advancements, including support for region subtyping and a coherent integration with stack allocation and a garbage collector. To support separate compilation, Cyclone requires programmers to write some explicit region annotations, but uses a combination of default annotations, local type inference, and a novel treatment of region effects to reduce this burden. As a result, we integrate C idioms in a region-based framework. In our experience, porting legacy C to Cyclone has required altering about 8\% of the code; of the changes, only 6\% (of the 8\%) were region annotations. This technical report is really two documents in one: The first part is a paper submitted for publication in November, 2001. The second part is the full formal language and type-safety proof mentioned briefly in the first part. If you have already read a version of, ``Region-Based Memory Management in Cyclone'', then you should proceed directly to Section 9.

title: What Energy Functions can be Minimized via Graph Cuts?
abstract: Many problems in computer vision can be naturally phrased in terms of energy minimization. In the last few years researchers have developed a powerful class of energy minimization methods based on graph cuts. These techniques construct a specialized graph, such that the minimum cut on the graph also minimizes the energy. The minimum cut in turn is efficiently computed by max flow algorithms. Such methods have been successfully applied to a number of important vision problems, including image restoration, motion, stereo, voxel occupancy and medical imaging. However, each graph construction to date has been highly specific for a particular energy function. In this paper we address a much broader problem, by characterizing the class of energy functions that can be minimized by graph cuts, and by giving a general-purpose construction that minimizes any energy function in this class. Our results generalize several previous vision algorithms based on graph cuts, and also show how to minimize an interesting new class of energy functions.

title: A Theory of Second-Order Trees
abstract: This report describes a theory of second-order trees, that is, finite and infinite trees where nodes of the tree can bind variables that appear further down in the tree. Such trees can be used to provide a natural and intuitive interpretation for type systems with equirecursive types and binding constructs like universal and existential quantifiers. The report defines the set of binding trees, and a subset of these called regular binding trees. These are similar to the usual notion of regular trees, but generalized to take into account the binding structure. Then the report shows how to interpret a second-order type system with recursive quantifiers as binding trees, and gives a sound and complete axiomatisation of when two types map to the same tree. Finally the report gives a finite representation for trees called tree automata, and gives a construction for deciding when two automata map to the same tree. To tie everything together, the report defines a mapping from types to automata, thus giving a decision procedure for when two types map to the same tree.

title: TAF: A Temporal Adaptation Framework for Hybrid Routing in Mobile AdHoc Networks
abstract: A central challenge in ad hoc networks is the design of routing protocols that can adapt their behavior to frequent and rapid changes at the network level. Choosing between reactive, proactive, or hybrid routing regimes and selecting appropriate configuration parameters for a chosen protocol are difficult tasks. This paper introduces a framework, called TAF, for seamlessly adapting between proactive and reactive routing protocols. This general framework enables a proactive and reactive protocol to coexist on the same network, provides a low-overhead mechanism by which these two routing strategies can be combined at fine grain and proposes an analytical model for automatically adjusting protocol parameters. Combined, this mechanism and model enable a protocol within our framework to find a near-optimal mix of proactive and reactive routing strategies for the mobility rate and traffic patterns observed on the network. We examine the application of this temporal adaptation framework to the construction of three specialized ad hoc rout- ing protocols. These protocols minimize packet overhead, achieve a targeted loss rate, and minimize routing latency using the TAF framework. In all three cases, hybrid protocols based on the TAF framework perform as well as or better than a proactive (TORA) and a reactive (AODV) protocol.

title: Bursty and Hierarchical Structure in Streams
abstract: A fundamental problem in text data mining is to extract meaningful structure from document streams that arrive continuously over time. E-mail and news articles are two natural examples of such streams, each characterized by topics that appear, grow in intensity for a period of time, and then fade away. The published literature in a particular research field can be seen to exhibit similar phenomena over a much longer time scale. Underlying much of the text mining work in this area is the following intuitive premise --- that the appearance of a topic in a document stream is signaled by a ``burst of activity,'' with certain features rising sharply in frequency as the topic emerges. The goal of the present work is to develop a formal approach for modeling such ``bursts,'' in such a way that they can be robustly and efficiently identified, and can provide an organizational framework for analyzing the underlying content. The approach is based on modeling the stream using an infinite-state automaton, in which bursts appear naturally as state transitions; in some ways, it can be viewed as drawing an analogy with models from queueing theory for bursty network traffic. The resulting algorithms are highly efficient, and yield a nested representation of the set of bursts that imposes a hierarchical structure on the overall stream. Experiments with e-mail and research paper archives suggest that the resulting structures have a natural meaning in terms of the content that gave rise to them.

title: Equational Verification of Cache Blocking in LU Decomposition using Kleene Algebra with Tests

abstract: In a recent paper of Mateev et al. (2001), a new technique for program analysis called fractal symbolic analysis was introduced and applied to verify the correctness of a series of source-level transformations for cache blocking in LU decomposition with partial pivoting. It was argued in that paper that traditional techniques are inadequate because the transformations break definition-use dependencies. We show how the task can be accomplished purely equationally using Kleene algebra with tests.

title: Quotient Types --- a Modular Approach
abstract: In this paper we introduce a new approach to defining quotient types in type theory. We suggest replacing the existing monolithic rule set by a modular set of rules for a specially chosen set of primitive operations. This modular formalization of quotient types turns out to be very powerful and free of many limitations of the traditional monolithic formalization. To illustrate the advantages of the new formalization, we show how the type of collections (that is known to be very hard to formalize using traditional quotient types) can be naturally formalized using the new primitives. We also show how modularity allows us to reuse one of the new primitives to simplify and enhance the rules for the set types.

title: On Fixed-Parameter Tractability of Some Routing Problems
abstract: Disjoint Paths is the problem of finding paths between given pairs of terminals in a graph such that no vertices are shared between paths. We analyze fixed-parameter tractability of several new Disjoint Paths-like routing problems motivated by congestion control in computer networks. In one model we are interested in finding paths between k pairs of terminals such that the first edge of each path is not shared with any other path. We prove that this problem is fixed-parameter tractable on directed graphs, in contrast to Disjoint Paths that are known to be NP-hard even for $k=2$. We improve our algorithm for two special cases: when the graph is acyclic and when all sources lie in distinct nodes. We consider extensions: a second-node-disjoint analog and a slightly generalized version of SAT. Another model, bottleneck-edge-disjoint paths, is a generalization of Disjoint Paths. For directed acyclic graphs, we show that bottleneck-edge-disjoint paths is $W[1]$-hard and hence unlikely to be fixed-parameter tractable. We give an algorithm that runs in time $n^{O(k)}$. These two results easily extend to Unsplittable Flows.

title: On the Elimination of Hypotheses in Kleene Algebra with Tests
abstract: The validity problem for certain universal Horn formulas of Kleene algebra with tests (KAT) can be efficiently reduced to the equational theory. This reduction is known as elimination of hypotheses. Hypotheses are used to describe the interaction of atomic programs and tests and are an essential component of practical program verification with KAT. The ability to eliminate hypotheses of a certain form means that the Horn theory with premises of that form remains decidable in PSPACE. It was known (Cohen 1994, Kozen and Smith 1996, Kozen 1997) how to eliminate hypotheses of the form q=0. In this paper we show how to eliminate hypotheses of the form cp=c for atomic p. Hypotheses of this form are useful in

eliminating redundant code and arise quite often in the verification of compiler optimizations (Kozen and Patron 2000).

title: Automated Computational Complexity Analysis
abstract: Program synthesis is the machine-assisted construction of provably correct programs from formal high-level specifications. Automated synthesis tools appeared soon after the introduction of theorem provers in the 1960s and, owing to a revived interest in the field during the 1990s, have now matured to a state in which they are routinely used in projects outside of research laboratories. Despite this success, however, program synthesis remains challenged by broadening demands for program quality, as for the next generation of synthesis tools the main focus shifts from program correctness to program efficiency. This thesis introduces our approach to automated computational complexity analysis and certification of higher-order functional programs as a means to resource-conscious program synthesis. First, we develop a general framework for expressing higher-order computational complexity of functional programs. Our compositional calculus is based on complexity annotations of an open-ended operational semantics and defines the complexity of a function as the cost of reducing the function term applied to a symbolic argument. Higher-type arguments are assigned a canonical computational skeleton whose decomposition exposes their internal structure. Second, we present algorithms that automatically generate and solve parameterized higher-type recurrence equations expressing the complexity of recursive functions. The recurrence generator uses symbolic evaluation to derive equations for primitive and general recursive terms. The recurrence solver reduces these equations to systems of unparameterized first-order recurrence equations that can be solved by conventional methods. A collection of simplification heuristics eliminates intractable functions by approximation. Third, we formalize our calculus and automate the construction of formal proofs that assert the correctness of the symbolic evaluation result. Proofs use a basic term reflection mechanism to reason intensionally about term evaluation at the meta-level. The Automated Complexity Analysis System implementation demonstrates the viability of our approach. The system uses the Nuprl proof development system and the Mathematica computer algebra system to compute the time complexity of Nuprl proof extracts. It has been able to identify automatically infeasible synthesized code whose manual discovery had taken many days previously.

title: Halting and Equivalence of Schemes over Recursive Theories
abstract: Let S be a fixed first-order signature. In this note we consider the following decision problems. (i) Given a recursive ground theory T over S, a program scheme p over S, and input values specified by ground terms t1,...,tn, does p halt on input t1,...,tn in all models of T? (ii) Given a recursive ground theory T over S and two program schemes p and q over S, are p and q equivalent in all models of T? When T is empty, these two problems are the classical halting and equivalence problems for program schemes, respectively. We show that problem (i) is r.e.-complete and problem (ii) is Pi-0-2-complete. Both these problems remain hard for their respective complexity classes even if T is empty and S is restricted to contain only a single constant, a single unary function symbol, and a single monadic predicate. It follows from (ii) that there can exist no relatively complete deductive system for scheme equivalence.

title: Some Results in Dynamic Model Theory
abstract: First-order structures over a fixed signature S give rise to a family of trace-based and relational Kleene algebras with tests defined in terms of Tarskian frames. A Tarskian frame is a Kripke frame whose states are valuations of program variables and whose atomic actions are state changes effected by variable assignments x := e, where e is an S-term. The Kleene algebras with tests that arise in this way play a role in dynamic model theory akin to the role played by Lindenbaum algebras in classical first-order model theory. Given a first-order theory T over S, we exhibit a Kripke frame U whose trace algebra Tr U is universal for the equational theory of Tarskian trace algebras over S satisfying T, although U itself is not Tarskian in general. The corresponding relation algebra Rel U is not universal for the equational theory of relation algebras of Tarskian frames, but it is so modulo observational equivalence.

title: Polyglot: An Extensible Compiler Framework for Java
abstract: Polyglot is an extensible compiler framework that supports the easy creation of compilers for languages similar to Java, while avoiding code duplication. The Polyglot framework is useful for domain-specific languages, exploration of language design, and for simplified versions of Java for pedagogical use. We have used Polyglot to implement several major and minor modifications to Java; the cost of implementing language extensions scales well with the degree to which the language differs from Java. This paper focuses on the design choices in Polyglot that are important for making the framework usable and highly extensible. Polyglot source code is available.

title: Meta Clustering
abstract: Most clustering methods search for one optimal partitioning of the data. Often it is better to search for many different clusterings of the data and present the user with a means of efficiently navigating between them. We present two algorithms for generating many alternate clusterings: Sample-and-Merge and Component Reweighting. We then use clustering at a meta level to organize these different base-level clusterings. This {\em MetaClustering} partitions the base-level clusterings into groups of similar clusterings. We demonstrate MetaClustering on a synthetic data set, and on a real protein data set. The results show that the algorithms are effective at generating qualitatively different clusterings, and at organizing these clusterings so that similar ones are grouped together.

title: Abstract Identifiers and Textual Reference
abstract: Here are three proposals concerning the structure and maintenance of formal, inter-referential,

digitally stored texts: (1) include abstract atomic identifiers in texts, (2) identify these identifiers with references to text objects, and (3) keep among the texts records of computationally substantiated claims about those texts. We use ``formal'' in a narrow sense approximating computer-checkable. We are informed by informal symbolic practices used in mathematical text and program source text, which we hope to enhance and exploit explicitly; the basic management problem is how to alter texts {\em rather} {\em freely} without ruining the bases for claims depending upon them, which becomes an issue of accounting for various dependencies between texts. We are {\em not} here proposing the use of abstract structured text; nonetheless, experience using it in Nuprl4 has led us to appreciate the benefits of distinguishing abstract form from concrete presentation, and also has shown us the cognitive and practical {\em un}importance of just which identifiers occur in abstract structured texts when texts are mediated by a system that realizes concrete presentation. Abstract treatment of identifiers involves concrete realization during communications between ``text servers'' and their clients. The benefit of treating identifiers abstractly is a radical avoidance of name collision, even at runtime, and is important for claims about texts that are based upon program execution. The notion of text collections and equivalence of text collections modulo change of identifiers is made precise by the second proposal. The complete identification of abstract identifiers with reference values is discussed, addressing the issues of dangling pointers, the association of ordinary symbolic identifiers with meaningful defining texts, the ``flatness'' of the pointer space, and the perhaps counterintuitive collapse of two abstract name spaces into one. The notion of ``certification system'' is introduced as a formalization of generic computationally defined claims about texts, emphasizing the diversity of clients who may not agree on a common ``logic''. The notion of a certificate whose computational meaning, in the context of the texts it refers to, is completely specified (although perhaps non-deterministic), and the notion of a certificate further being deterministic, are introduced and elaborated with regard to their epistemic value. What it means to give certificate texts the force of factual records, and mechanisms to accomplish this, are discussed. Scenarios for practically exploiting identifier abstractness and fully deterministic certificates are considered, involving the combination of partially independently developed texts and the experimental modification of texts in a collection. The importance of implementing multiple certification systems is articulated.

title: Network Failure Detection and Graph Connectivity
abstract: We consider a model for monitoring the connectivity of a network subject to node or edge failures. In particular, we are concerned with detecting \emph{$(\vareps, k)$-failures}: events in which an adversary deletes up to k network elements (nodes or edges), after which there are two sets of nodes A and B, each at least an $\vareps$ fraction of the network, that are disconnected from one another. We say that a set D of nodes is an $(\vareps, k)$-detection set if, for any $(\vareps, k)$-failure of the network, some two nodes in D are no longer able to communicate; in this way, D ``witnesses'' any such failure. Recent results show that for any graph G, there is an $(\vareps, k)$-detection set of size bounded by a polynomial in k and $\vareps$, independent of the size of G. In this paper, we expose some relationships between bounds on detection sets and the edge-connectivity λ and node-connectivity κ of the underlying graph. Specifically, we show that detection set bounds can be made considerably stronger when parametrized by these connectivity values. We show that for an adversary that can delete λ edges, there is always an $(\vareps, \lambda)$-detection set of size at most $\freps$, and an $(\vareps, \lambda)$-detection set of minimum size can be computed in polynomial time. A crucial point is that this bound is independent not just of the size of G but also of the value of λ. Our bounds extend to adversaries that can delete up to $k \lambda$ edges for $k > 1$. We also show an analogous bound of $O(\frac{1}{\vareps})$ on the size of detection sets for adversaries that can delete κ nodes. Our algorithm for $(\

vareps, \lambda)$-edge failures is based on the cactus representation of all minimum edge-cuts of a graph; for node failures, we develop a novel approach for working with the much more complex set of all minimum node-cuts of a graph.

title: Discrete Hedging Under Piecewise Linear Risk-Minimization
abstract: In an incomplete market it is usually impossible to eliminate the intrinsic risk of an option. In this case, quadratic-risk minimization is often used to determine a hedging strategy. However, it may be more natural to use piecewise linear risk-minimization. We investigate hedging strategies using piecewise linear risk-minimization. We illustrate that this criterion for risk-minimization may lead to smaller expected total hedging cost and significantly different, possibly more desirable, hedging strategies from those of quadratic risk-minimization. The distributions of the total hedging cost and risk show that hedging strategies obtained by piecewise linear risk-minimization have a larger probability of small cost and risk, though they also have a very small probability of larger cost and risk. Comparative numerical results are provided. We also prove that the value processes of these hedging strategies satisfy put-call parity.

title: On the Recognition of Primes by Automata
abstract: A study of the problem of recognizing the set of primes by automata is presented. A simple algebraic condition is derived which shows that neither the set of primes nor any infinite subset of primes can be accepted by a pushdown or finite automaton. In view of this result an interesting open problem is to determine the "weakest" automaton which can accept the set of primes. It is shown that the linearly bounded automaton can accept the set of primes, and it is conjectured that no automaton whose memory grows less rapidly can recognize the set of primes. One of the results shows that if this conjecture is true, it cannot be proved by the use of arguments about the distribution of primes, as described by the Prime Number Theorem. Some relations are established between two classical conjectures in number theory and the minimal rate of memory growth of automata which can recognize the set of primes.

title: The Use of Standardized Documentary Data in AutomaticInformation Dissemination
abstract: It is likely that future operating information retrieval systems may be based on automatic information analysis methods instead of manual indexing, and on search procedures which allow the user to interact with the system during the search process. The effectiveness of the required analysis and search operations depends to some extent on the availability in machine readable form of standardized information concerning the make-up and content of each stored document. An author-prepared standard manuscript documentation unit, furnished with each manuscript, may simplify the information retrieval and dissemination operations, and improve their effectiveness. The design of such a documentation unit is covered and its use is explained for indexing, classification, vocabulary normalization, searching, and retrieval.

title: The Representation and Transformation of Functions
abstract: A new approach to the study of programming languages is developed, which emphasized the sequence of information structures generated by a program during its execution. In section 1 a class of models called information structure models is developed for characterizing computations as sequences of transformations of information structures. The notion of binding time is introduced and different binding strategies for programming languages are considered. Section 2 considers the representation of functions by symbol tables and analyzes a number of examples of such functions, such as assemblers and macro systems. Section 3 introduces a very simple programming language for funcitn evaluation known as the lambda calculus, and considers information structure models for alternative evaluation strategies in the lambda calculus. Section 4 shows that ALGOL computations can be specified as information structure models with the same basic characteristics as lambda calculus computations but with a richer set of primitives, and indicates how languages such as PL/I can be characterized as information structure models.

title: Concepts and Structures in Programming Languages
abstract: These notes develop a set of concepts for describing program structures which arise in programming languages. These concepts are then used to discuss FORTRAN, ALGOL, macro languages, languages with definitional facilities, SNOBOL4, and LISP from a unifying point of view. The central concept is that of an information structure model. Emphasis is placed on the sequence of information structures generated by programs of a programming language during their execution. Section 1 considers program representation, interpretation, and compilation. Section 2 introduces the concept of an information structure model for characterizing classes of computations. Sections 3 and 4 show that computers and programming languages are examples of information structure models. Sections 5 and 6 respectively consider the information structures associated with FORTRAN and ALGOL programs during their execution. Section 7 shows how syntax and

semantics may be specified for information structure models and introduces the notion of an interpreter-interpreter. Section 8 develops information structure models for macro languages. Section 9 introduces the concept of binding time and discusses declarations and definitional facilities in programming languages. Sections 10 and 11 consider information structure models for SNOBOL4 and LISP. Computer science may be defined as the study of representation and transformation of information structures. The present approach is concerned with the representation of programs as information structures and with the transformations of these structures during execution, and directly reflects the above definition of computer science.

title: On the Equivalence and Containment Problems for Context-Free Languages
abstract: Let G and G_{0} be context-free grammars. Necessary and sufficient conditions on G_{0} are obtained for the decidability of $L(G_{0}) \subseteq L(G)$. It is also shown that it is undecidable for which $G_{0},L(G) \subseteq L($G_{0})$ is decidable. Furthermore, given that $L(G) \subseteq L($G_{0})$ is decidable for a fixed G_{0}, there is no effective procedure to determine the algorithm which decides $L(G) \subseteq L($G_{0})$. If $L(G_{0})$ is a regular set, $L(G)=L(G_{0})$ is decidable if and only if $L(G_{0})$ is bounded. However, there exist non-regular, unbounded $L(G_{0})$ for which $L(G) = L(G_{0})$ is decidable.

title: DPL: A Language for Instruction in CONTEMPORARY DATA PROCESSING CONCEPTS
abstract: The Data Processing Language (DPL) id designed with two aims. The first is to aid in teaching the concepts and techniques of contemporary data processing systems to those who need an appreciation of the field, but who do not need to become trined programmers. The second is to test a new method for organizing and programming large systems which share a common data base among several simultaneous users. The criteria for a contemporary data processing language are set forth and DPL is shown to meet them. These include remote terminal management, handling of shared data bases, file and device oriented input and output, and standard arithmetic and text processing features. In addition, simple syntax and extensive error detection and correction features fulfill important requirements of instructional computing systems. Interrupts are the basis for the new method of systems organization. The DPL programmer can specify conditions when interrupts should be generated, e.g., when the relation $X+Y=34$ is true, and can specify the routine which should be called to process each interrupt. The DPL monitoring system detects the occurrence of these conditions and generates the interrupts. Some of these variables involved in conditions which can generate interrupts may be in files. The programmer can attach to those files the interrupt processing routines and the interrupt conditions. When the file is read in, the system begins monitoring these attached interrupt conditions and may execute the attached interrupt processing routines, which are called file tags, even though the user who placed the tags on the file is no longer in control. Several interrupts may be generated as the result of the execution of a single DPL statement, and interrupts may be generated while executing an interrupt processing routine. Therefore, an algorithm is presented which schedules the execution of the interrupt processing routines. A management information system may thus be composed of two parts: a data base of tagged files, and a supervisor program which handless interaction with remote terminals and performs background tasks. This new organization is shown to have value both for its instructional clarity and for designing and programming large integrated information systems.

title: Relevance Assessments and Retrieval System Evaluation
abstract: Two widely used criteria for evaluating the effectiveness of information retrieval systems are, respectively, the recall and the precision. Since the determination of these measures is dependent on a distinction between documents which are relevant on the one hand, and documents which are not relevant on the other to a given query set, it has sometimes been claimed that an accurate, generally valid evaluation cannot be based on recall and precision. A study was made to determine the effect of variations in relevance assessments on the average recall and precision values used to measure retrieval effectiveness. Using a collection of 1200 documents in information science for test purposes, it is found that large scale differences in the relevance assessments do not produce significant variations in average recall and precision. It thus appears that properly computed recall and precision data may represent effectiveness indicators which are generally valid for many distinct user classes.

title: Computational Complexity of One-Tape Turing Machine Computations
abstract: This paper is concerned with the quantitative aspects of one-tape Turing machine computations. It is shown, for instance, that there exists a sharp time bound which must be reached for the recognition of non-regular sets of sequences. It is shown that the computation time can be used to characterize the complexity of recursive sets of sequences and several results are obtained about this classification. These results are then applied to the recognition speed of context-free languages and it is shown, among other things, that it is recursively undecidable how much time is required to recognize a non-regular context-free language on a one-tape Turing machine. Several unsolved problems are discussed.

title: Tape Reversal Bounded Turing Machine Computations
abstract: This paper studies the classification of recursive sets by the number of tape reversals required for their recognition on a two-tape Turing machine with a one-way input tape. This measure yields a rich hierarchy of tape reversal limited complexity classes and their properties and ordering are investigated. The most striking difference between this and the previously studied complexity measures lies in the fact that the "speed-up" theorem does not hold for slowly growing tape reversal complexity classes. These differences are discussed, and several relations between the different complexity measures and languages are established.

title: The Structure of SNOBOL4
abstract: The SNOBOL4 programming language was developed by Griswold, Poage and Polonski (1). It combines facilities available in problem oriented languages with string manipulation facilities, pattern matching facilities and facilities for compilation during execution. The present description attempts to accomplish three objectives. It is an introduction to SNOBOL4 for the programmer with previous programming experience in some programming language but not necessarily previous experience with SNOBOL3. It is intended also to provide dynamic insights into the mechanisms for statement execution, and to describe source language structures in terms of the information structures to which they give rise during execution. It is felt that dynaamic insights into the way in which source statements are executed help not only the system programmer but also the average user. This description is based on reference 1 and on two very worthwhile days of discussion with the authors of SNOBOL4 at Holmdel. The author is indebted also to John Kelly for fruitful discussion of aspects of SNOBOL4 and for proofreading the manuscript.

title: Dynamic File Organization and Heuristic SearchStrategies in Information Retrieval
abstract: A great deal of effort has been devoted in recent years to the evaluation of automatic or semi-automatic information retrieval systems. Recent evaluation results indicate that the search effectiveness presently achieved, or likely to be achievable in the foreseeable future, is much smaller than expected by a majority of the potential user population. Furthermore, theoretical advances in language analysis and data organization promise only relatively modest future improvements. The most significant advances in retrieval effectiveness are likely to be obtained by using adaptive techniques to extract information from the user population during the search process, leading to an improved organization of the data space and to more effective search and retrieval operations. Various user feddback techniques are described producing either modifications in the user queries i such a way as to bring these queries closer to existing groups of relevant documents, or modifications in the document space to bring relevant documents closer to the corresponding search requests. The feedback and space modification techniques are examined in detail, and the resulting efficiencies in the remote and retrieval operations are described. Descriptive Terms: Information retrieval, document retrieval, user feedback, relevance feedback, request modifications, document modifications, document grouping, clustering, adaptive search method, cluster searches, search effectiveness.

title: Upward and Downward Diagonalization over Axiomatic Complexity Classes
abstract: This report considers special cases of the question “”What conditions on u() and t() guarantees that $R^{\Phi}_{t}() \neq $R^{\Phi}_{u}()$?” where $R^{\Phi}_{t}()$ is the class of recursive functions whose Φ complexity is bounded by t(). In particular the condition $\stackrel{inf}{n\rightarrow\infty} \frac{t(n)}{u(n)} = 0$ and $\stackrel{lim}{n\rightarrow\infty} \frac{t(n)}{u(n)} = 0$ are examined, and it is shown that certain results of Hartmanis, Stearns and Hennis are in one sense the best possible. It is then shown that the diagonalization techniques used in results of this type are of two different sorts, upward and downward. The differences are made precise and very general conditions are found under which each type applies. These conditions widely generalize several well-known results for time and tape complexity measures. In the final section, the report considers some properties of a special class of names for complexity classes. The techniques used in Lemma 3.3 and Theorems 5.1 and 7.1 are new and promise wider application. Also, new results of Borodin and McCreight and Meyer are used, but otherwise the methods are those of Blum.

title: Parsing of Graph-Representable Pictures
abstract: This paper describes a syntax-directed picture analysis system based on a formal picture description

scheme. The system accepts a description of a set of pictures in terms of a grammar generating strings in a picture description language; the grammar is explicitly used to direct the analysis or parse, and to control the calls on pattern classification routines for primitive picture components. Pictures are represented by directed graphs with labelled edges, where the edges denote elementary picture components and the graph connectivity mirrors the picture component connectivity; blank and don't care "patterns" allow the description of simple relations between visible patterns. The bulk of the paper is concerned with the picture parsing algorithm which is an n-dimensional analog of a classical top-down string parser, and an application of an implemented system to the analysis of spark chamber film. The potential benefits of this approach, as demonstrated by the application, include ease of implementation and modification of picture processing systems, and simplification of the pattern recognition problem by automatically taking advantage of contextual information. Key Phrases: picture processing, picture parsing, picture description, picture analysis, pattern recognition, top-down analyzer, graph representable pictures, syntax directed analysis, picture language, picture grammar, graphics language.

title: The Operator Gap
abstract: This paper continues investigations pertaining to recursive bounds on computing resources (such as time or memory) and the amount by which these bounds must be increased if new computations are to occur within the new bound. The paper proves that no recursive operator can increase every recursive bound enough to reach new computations. In other words, given any general recursive operator F[], there is an arbitrarily large recursive t() such that between bound t() and bound F[t()]() there is a gap in which no new computation runs. This demonstrates that the gap phenomenon first discovered by Borodin for composition is a deeply intrinsic property of computational complexity measures. Moreover, the Operator Gap Theorem proved here is shown to be the strongest possible gap theorem for general recursive operators. The proof involves a priority argument but is sufficiently self-contained that it can easily be read by a wide audience. The paper also discusses interesting connections between the Operator Gap Theorem and McCreight and Meyer's important result that every complexity class can be named by a function from a measured set.

title: On the Feasibility of Voice Input to an On-Line Computer Processing System
abstract: An on-line digital computer processing system is considered in which an ordinary telephone is the complete terminal device, input to the computer being provided as a sequence of spoken words, and output to the user being audio responses from the machine. The feasibility of implementing such a system with a FORTRAN-LIKE algebraic compiler as the object processor is considered. Complete details of a specific word recognition program are given. This technique depends on three simplifying restrictions, namely, a "small" vocabulary set, "known" speakers, and a "moment of silence" between each input word. Experimental results are presented giving error rates for different experimental conditions as well as the machine resources required to accomodate several users at a time. The results show that at this time it is both economically and logically feasible to handle at least 40 users at a time with an IBM 360/65 computer.

title: Evaluation Problems in Interactive Information Retrieval
abstract: Interactive retrieval procedures are normally based on rapidly accessible files. Special storage organizations and file search techniques are used, and the system user is made to fulfill an important role during the retrieval process. In the present study, the interactive retrieval environment is briefly examined. The special problems which arise in the evaluation of interactive retrieval are then discussed, and methods are described for evaluating partial file searches and user feedback techniques. Evaluation resultss obtained with the SMART system are presented.

title: Interactive Information Retrieval
abstract: The advent of time-sharing computer organizations and input-output console equipment has made it possible to experiment with interactive information handling methods in which the user takes on important functions both in planning and in executing information searches. The principal interactive text storage and retrieval processes are briefly reviewed, including text editing, text analysis and indexing, query formulation, and information searching. The user's role is stressed in each case, and particular attention is paid to interactive search procedures in which both the user queries and the stored information files become altered as a result of the user-system interaction. Evaluation results obtained with the SMART retrieval system are exhibited for some of the proposed methodology.

title: On the Automatic Calculation of Solutions - Different from Those Previously Obtained - of Nonlinear Systems of Equations
abstract: Given a system of N nonlinear (algebraic or transcendental) real equations in N real unknowns, there exist a variety of numerical methods which obtain solutions of those equations. This paper presents two methods which are used to find further simple solutions - in addition to those already known a priori or from an earlier calculation. These methods have the advantage of keeping away from solutions previously calculated, saving the computer user the wasted effort entailed in converging to already known, perhaps uninteresting solutions points. The technique can also be used in avoiding previously found extreme points in function minimization. Many problems have "magnetic zeros", zeros which are converged to almost regardless of the starting guesses used. These magnetic zeros often mask out the zeros of real interest. The methods discussed are particularly effective in avoiding convergence to such magnetic zeros. Results of computer experiments ar presented.

title: 'I Heard Beauty Dying': The Cultural Critique of Plastic in Gravity's Rainbow
abstract: This essay attempts to get a grasp on Pynchon's 700-plus page omnibus, Gravity's Rainbow, by focusing on the development of a single motif in the novel: plastic. It argues that Pynchon takes 1960s and 1970s critiques of supply-driven consumer capitalism, of which plastic was a visible emblem, and makes them more emphatic by placing them into a fictionalized version of the prewar years and the 1940s. Looking backwards, and employing a creative license that allows him to attribute the rise of plastics technology and consumer capitalism to purposely evil entities (like his fictional versions of real-life corporations IG Farben and Shell Oil), Pynchon is able to deliver a narrative that locates the roots of contemporary problems in the technological and business innovations of the World War II era. In Gravity's Rainbow, as in early-'70s America, plastic comes to signify for a suite of negative meanings, from environmental degradation, to an exploitative economic order, to a sadistic psychology in which the desire to achieve immortality results in the destruction and perversion of life itself. The essay is divided into three sections. The first uses a cultural history of plastic to identify popular cultural attitudes towards plastic and locate them in Pynchon's text. The second turns towards a closer reading of Gravity's Rainbow, examining the character Greta Erdmann and her relationship to plastic. The final section considers a second character, Tyrone Slothrop, and concludes that Pynchon's critique of plastic ends on a pessimistic note, positing only a limited possibility for meaningful resistance towards plastic and the material and psychological economies that it represents.

title: Reducing Ventilation Energy Demand In Multifamily High Rise Buildings Through Preconditioning: Two Modeling Studies
abstract: Concerns over climate change and rising costs and demand of energy have fueled interest in various renewable and high efficiency energy technologies in recent years.
The energy demand associated with ventilation in high rise multifamily buildings can be quite significant. A number of technologies have been developed with the aim of reducing the demand associated with the maintenance of acceptable levels of indoor air quality and comfort in residential buildings.
Two such technologies were studied here. The unglazed transpired solar collector (UTSC) represents a radical shift from earlier collector designs with its perforated metal cladding and the absence of glazings and covers.

It acts as a ventilation air preheater by delivering warmed air to a conventional makeup air heater which supplies any necessary supplemental heating prior to building delivery. The perforated design allows the boundary layer to be sucked into the collector, resulting in very high thermal efficiencies.
A model consisting of a UTSC system and the building on which it is installed was developed. The model computes hourly performance based on TMY2 weather data. Results indicated the importance of the control system in maximizing energy capture and validated the realistic option of a nighttime bypass mode. Results of simulations in seven locations across the state of New York indicated that, while substantial energy capture was possible, economic performance appeared to be marginal.
Recovery ventilation (including both heat and energy recovery ventilation) offers another potentially attractive method of offsetting ventilation energy demand by preconditioning ventilation air. Heat and/or moisture are transferred between the exhaust and supply streams of the ventilation system, allowing the capture of ?waste? heat and moisture (or the lack of these two, depending on the season) from the exhaust stream. Recovery ventilation, which can also achieve very high efficiencies, has the advantage over solar technologies of operating continuously and unimpeded during both day and night and throughout the entire year since the heat/moisture exchange proceeds in either direction and is useful in both.
Unfortunately, serious problems hampering the field performance of recovery ventilation systems have included low system flows and pressures and even flow reversal at exhaust terminals. A model of a typical high rise residential building was developed based on an existing Albany building involved in a recovery ventilation case study and exhibiting these problems. The model successfully predicted the key field observations of low pressures and flows along with flow reversal under certain conditions. Factors found to significantly affect ventilation system performance included stack effect, opening of windows, and duct leakage. Possible solution strategies were investigated including increasing system pressure, compartmentalization, and leakage reduction. An important finding was that typical operating pressures are most likely too low to resist external disturbances such as stack effect. However, significant duct leakage can pose a formiddable obstacle to achieving higher pressure systems. These results indicate the importance of considering both the necessary pressures for immunization against uncontrollable disturbances and the duct leakage present (in retrofit applications) in order to maximize the performance of recovery ventilation systems in the field.

title: An Error Analysis for Functions of Qualitative Attributes with Application to Information Retrieval
abstract: The use of overlapping, non-hierarchical classifications in information retrieval is considered. It is assumed that the population of objects to be classified is such that only a subset of the classes satisfying the classificatory criterion may be found. The effect of this assumption on the measurement of classification stability is considered. As a step towards the determination of stability, a general technique is presented for deriving the expectation of a statistical function of the similarities between the objects of the population. It is assumed that the objects are describable in terms of two-state attributes which are susceptible independently and equiprobably to error with an assignable probability. Two commonly encountered similarity functions are treated in detail. The techniques disclosed are applicable, in principle, to classification algorithms, whether hierarchical or non-hierarchical, which utilize a similarity matrix giving the similarities between pairs of objects described by two-state independent attributes.

title: On the Size of Programs in Subrecursive Formalisms
abstract: This paper gives an overview of subrecursive hierarchy theory as it relates to computational complexity and applies some of the concepts to questions about the size of programs in subrecursive programming languages. The purpose is three-fold, to reveal in simple terms the workings of subrecursive hierarchies, to indicate new results in the area, and to point out ways that the fundamental ideas in hierarchy theory can lead to interesting questions about programming languages. A specific application yields new information

about Blum's results on the size of programs and about the relationship between size and efficiency.

title: The Weakening of Taxonomic Inferences by Homological Errors
abstract: In the past decade there has been a growing concern in devising classification algorithms which are applicable to large bodies of data. Such algorithms are characterized necessarily by a sacrifice of statistical sophistication for a gain in computational simplicity. Accordingly, inferences drawn from taxonomic studies in which these algorithms have been employed may be affected by accidental and poorly understood features of such algorithms. An error analytic technique is presented which reduces this possibility. It is applicable to many of the classification algorithms currently in use. The combinatorial problems encountered in the error analysis are discussed and a computationally viable method for their solution is formulated. The technique is illustrated by an experiment with a small set of data.

title: Computational Complexity of Random Access Stored Program Machines
abstract: In this paper we explore the computational complexity measure defined by running times of programs on random access stored program machines, RASP'S. The purpose of this work is to study more realistic complexity measures and to provide a setting and some techniques to explore different computer organizations. The more interesting results of this paper are obtained by an argument about the size of the computed functions. For example, we show (without using diagonalization) that there exist arbitrarily complex functions with optimal RASP programs whose running time cannot be improved by any multiplicative constant. We show, furthermore, that these optimal programs cannot be fixed prodecures and self-modifying programs. The same technique is used to compare computation speed of machines with and without built in multiplication. We conclude the paper with a look at machines with associative memory and distributed logic machines.

title: Size Arguments in the Study of Computation Speeds
abstract: In this paper we use arguments about the size of the computed functions to investigate the computation speed of Turing machines. It turns out that the size arguments yield several new results which we have not been able to obtain previously by diagonalization. For example, we show that for arbitrarily complex running times $T(n)$ there exist functions which can be computed on a one-tape Turing machine in time $T(n)$ but not in time $t(n)$ provided $\stackrel{\lim}{n \rightarrow \infty} \frac{t(n)}{T(n)}=0$. The same result is also shown to hold for many-tape machines. We show furthermore, that there exist arbitrarily complex computations for which one-tape machines are slower than two-tape machines by a factor equal to the logarithm of the computation time of the two-tape machine. We conclude by discussing several other computational complexity measures and compare results obtained by diagonalization and size arguments.

title: Common Phrases and Minimum-Space Text Storage
abstract: A method for saving storage space for text strings, such as compiler diagnostic messages, is described. The method relies on hand-selection of a set of text-strings which are common to one or more messages. These phrases are then stored only once. The storage technique gives rise to a mathematical optimization problem: determine how each message should use the available phrases to minimize its storage requirement. This problem is non-trivial when phrases which overlap exist. However, we present a dynamic programming algorithm which solves the problem in time which grows linearly with the number of characters in the text. Keywords and Phrases: diagnosic messages, error messages, common phrases, minimum space, text storage, optimization, dynamic programming.

title: Numerical Approximations to Expectations of Functions of Binary Sequences Subject to Error

abstract: There is growing interest in devising non-statistical classification algorithms for multivariate populations. Statistical algorithms are avoided either because they are too costly, or because an adequate statistical model for the population does not exist (e.g. use of trainable linear machines in pattern recognition). Such algorithms may be sensitive (unstable) to errors in their data. The particular case of populations of objects characterised by binary attributes susceptible to independent and equiprobable errors is examined. The determination of stability requires the prior computation of the expectation of a statistical function of the object-pair similarities. The order and convergence of a numerical approximation for determining these expectations with prescribed accuracy is examined in the sub-asymptotic case in which normality does not occur. A number of results are given.

title: On the Efficiency of a Good but Not Linear Set Union Algorithm
abstract: Consider two types of instructions for manipulating disjoint sets. FIND(x) computes the name of the (unique) set containing element x. UNION(A,B,C) combines sets A and B into a new set named C. We examinee a known algorithm for implementing sequences of these instructions. We show that if f(n) is the maximum time required by any sequence of n instructions, $k_{1} n \alpha (n) \leq f(n) \leq k_{2} n \log^{*} (n)$ for some constants k_{1} and k_{2}, where $\log^{*}(n) = \min\{i|\log^{i}(n) \leq 1\}$ and $\alpha(n)$ is a recursively defined function which satisfies $\alpha(n) \rightarrow \infty$ as $n \rightarrow \infty$. Thus the set union algorithm is $O(n \log^{*}(n))$ but not $O(n)$. Keywords and phrases: algorithm, complexity, equivalence, partition, set union, tree.

title: Constructive Mathematics and Automatic Program Writers
abstract: One point made here is that formal constructive mathematics can be interpreted as a “high-level” programming language; another point is that there are good reasons for doing so. Among them is the fact that a theoretical basis for automatic program writers (APW’s) becomes especially perspicuous (in such a context the problem of assigning meaning to programs a la Floyd [6] is the inverse of program writing). Another reason is that such an interpretation reveals a number off interesting mathematical problems in the theory of computing. While making these points we find occasion to present new observations on the completeness and efficiency of automatic program writers and to formulate a specific example of what we call von Neumann’s principle on the logical complexity of systems. We apply the principle in the automatic program writing context and discuss its more general ramifications about the intelligibility of programs.

title: The Symbolic Computation of Functions of Sequences over Finite Alphabets with Given Transition Probabilities by Sequence Length Independent Algorithms
abstract: A special case of the problem discussed in this paper occurs in connection with non-statistical classification and is introduced from this point of view. The special case concerns the computation of expectations of statistical functions of the "distance" between pairs of fixed length sequences over a binary alphabet with given a priori state transition probabilities. The general problem involves an extension to alphabets of arbitrary order and the comparison of an arbitrary number of fixed length sequences. Given a set of sequences, it is shown that for a large class of functions exact computation may be carried out by an algorithm whose computation time is independent of the length of the sequences. It is further shown that results for all functions of this class may be derived from a small number of basis functions. Two methods for computing basis functions are given. Basis functions for the commonly encountered special case involving pairs of binary sequences are given explicitly.

title: A Characterization of Superlinear Convergence and its Application to Quasi-Newton Methods
abstract: Let F be a mapping from real n-dimensional Euclidean space into itself. Most practical algorithms for finding a zero of F are of the form $x_{k+1} = x_{k} - B_{k}^{-1_{Fx_{k}}}$ where $\{B_{k}\}$ is a sequence of non-singular matrices. The main result of this paper is a characterization theorem for the superlinear convergence to a zero of F of sequences of the above form. This result is then used to give a unified treatment of the results on the superlinear convergence of the Davidon-Fletcher-Powell method obtained by Powell for the case in which exact line searches are used, and by Broyden, Dennis, and More for the case without line searches. As a by-product, several results on the asymptotic behavior of the sequence $\{B_{k}\}$ are obtained. An interesting aspect of these results is that superlinear convergence is obtained without any consistency conditions; i.e. without requiring that the sequence $\{B_{k}\}$ converge to the Jacobian.

title: Design and Implementation of a Diagnostic Compiler for PL/I
abstract: PL/C is a compiler for a dialect for PL/I. The design objective was to provide a maximum degree of diagnostic assistance in a batch processing environment. For the most part this assistance is implicit and is provided automatically by the compiler. The most remarkable characteristic of PL/C is its perseverance -- it completes translation of every program submitted and continues execution until a user-established error limit is reached. This requires that the compiler repair errors encountered during both translation and execution, and the design of PL/C is dominated by this consideration. PL/C also introduces several explicit user-controlled facilities for program testing. Some are conventional, providing a convenient high-level trace and dump capability. An experimental version of PL/C also permits the user to controllably reverse the direction of program execution and to write routines that are asynchronously invoked when an arbitrary condition becomes true. To accomodate these extensions to PL/I without abandoning compatibility with the

IBM compiler, PL/C permits `pseudo-comments' - constructions whose contents can optionally be considered either source text or comment. In spite of th ediagnostic effort PL/C is a fast and efficient processor. It effectively demonstrates that compilers can provide better diagnostic assistance than is customarily offered, even when a sophisticated source language is employed, and that this assistance need not be prohibitively costly. Key Words and Phrases: Compilers, Debugging, PL/I

title: On the Matrix Polynomial, Lamda-Matrix and Block Eigenvalue Problems
abstract: A matrix S is a solvent of the matrix polynomial $M(X) \equiv X^{m} + A_{1}X^{m-1} + \cdots + A_{m}$, if $M(S) = \stackrel{0}{=}$, where A_{1}, X and S are square matrices. We present some new mathematical results for matrix polynomials, as well as a globally convergent algorithm for calculating such solvents. In the theoretical part of this paper, existence theorems for solvents, a generalized division, interpolation, a block Vandermonde, and a generalized Lagrangian basis are studied. Algorithms are presented which generalize Traub's scalar polynomial methods, Bernoulli's method, and eigenvector powering. The related lambda-matrix problem, that of finding a scalar λ such that $I \lambda^{m} + A_{1} \lambda^{m-1} + \cdots + A_{m}$ is singular, is examined along with the matrix polynomial problem. The matrix polynomial problem can be cast into a block eigenvalue formulation as follows. Given a matrix A of order mn, find a matrix X of order n, such that $AV=VX$, where V is a matrix of full rank. Some of the implications of this new block eigenvalue formulation are considered.

title: The Application of Variational Inequalities to Complementarity Problems and Existence Theorems
abstract: If $F : C \rightarrow R^{n}$ is a continuous (nonlinear) mapping on a closed, convex subset C of R^{n}, it is shown that very weak coercivity conditins on F guarantee the existence of a solution x^{*} in C to the variational inequality $(x-x^{*}, Fx^{*}) \geq 0$ for each x in C. By restricting the shape of C, it is shown that x^{*} solves different problems, and in each case we are able to obtain new existence results. If C is a cone K, the x^{*} is a solution to the complementarity problem: Find an x^{*} in K such that Fx^{*} belongs to the polar of K and $(x^{*}, Fx^{*})=0$. In this case it is possible to generalize some of the feasibility results available in the linear theory and to give an iterative scheme for finding x^{*}. If C is similar to a simplex then x^{*} turns out to be a solution of nonlinear inequalities in the preorder induced by a cone, while if C or K is R^{n}, then $Fx^{*} =0$.

title: Algorthms for Rational Function Arithmetic Operations
abstract: Despite recent advances in speeding up many arithmetic and algebraic algorithms plus an increased concern with algorithm analysis, no computing time study has ever been done for algorithms which perform the rational function arithmetic operations. Mathematical symbol manipulation systems which provide for operations on rational functions use algorithms which were initially given by P. Henrici in 1956. In this paper, these algorithms are precisely specified and their computing times analyzed. Then new algorithms based on the use of modular arithmetic are developed and analyzed. It is shown that the computing time for adding and taking the derivative of univariate rational functions is 2 orders of magnitude faster using the modular algorithms. Also, the computing time for rational function multiplication will be one order of magnitude faster using the modular algorithm. The new method is generalized to the multivariate case and extensive empirical results are given. Keywords: Rational functions, modular arithmetic, arithmetic oeprations, algebraic algorithms.

title: A New Comparison Between Conventional Indexing (MEDLARS) andAutomatic Text Processing (SMART)
abstract: A new testing process is described designed to compare conventional retrieval (MEDLARS) and automatic text analysis methods (SMART). The results obtained with a collection of documents chosen independently of either SMART or MEDLARS indicate that a simple automatic extraction of keywords from document abstracts produces a 30 to 40 percent loss compared with MEDLARS indexing. A replacement of the unranked Boolean searches used in MEDLARS by the standard ranked output normally provided by SMART reduces the loss to between 15 and 20 percent. When an automatically generated word control list or a thesaurus is used as part of the SMART analysis, the results are comparable in effectiveness to those obtained by the intellectual MEDLARS indexing. Finally, the incorporation of user feedback procedures into SMART furnishes an improvement over the normal MEDLARS output of 15 to 30 percent. One concludes

again that no technical justification exists for maintaining controlled, manual indexing in operational retrieval environments.

title: Automatic Correction of Syntax Errors in Programming Languages
abstract: A very substantial fraction of the time and efforts required to develop a program is devoted to the removal of errors. In order to simplify this task, a model to automatize the correction of syntax errors is developed. It is the first model which is both formal and fairly realistic to appear in the literature. The notion of error is defined and studied formally. Then, using this definition, a systematic error-correction process is modelled. This process makes local corrections over clusters of errors, using the context around the errors to determine the corrections and to insure that the different local corrections performed on the string do not interfere with one another. The error-correction process can be naturally embedded in many left-to-right syntax checking processes. It uses the recognizer both to detect errors and to find possible corrections. The process has two modes: a ``standard mode'' used for syntax checking and an ``error-correction mode'' used for determining the context of a cluster of errors and for finding all possible corrections of these errors. In the ``standard mode'', the syntax is checked at the same speed as if no error-correction mechanism is implemented. Thus, for programs which contain no errors, no price is paid for the presence of this mechanism. The ``error-correction mode'' consist of two phases: the backward move which locates the left context of the cluster, and the forward move which construct possible corrections and locates the right context of the cluster. This process seems the most natural way to perform left-to-right syntax checking and error correction. Some techniques for efficiently finding the range of the backward move are developed. The formal model is not practical when using the conventional context-free description of programming languages. In order to make it more practical, the notion of bracketed context-free language is introduced and proposed as a model for the syntax fo programming languages. Then, heuristic restrictions on the type of errors corrected are discussed. They may lead to a simpler process. In particular, assuming that brackets are corrected only when no other correction is possible, and that errors in deep levels of nesting (with respect to the point where the errors are detected) are neglected, it is shown how the process can be used to correct syntax errors in programming languages.

title: A Unified View of the Complexity of Evaluation and Interpolation
abstract: Four problems are considered: 1) from an n-precision integer compute its residues modulo n single precision primes; 2) from an n-degree polynomial compute its values at n points; 3) from n residues compute the unique n-precision integer congruent to the residues; 4) from n points compute the unique interpolating polynomial through those points. If $M(n)$ is the time for n-precision integer multiplication, then the time for problems 1 and 2 is shown to be $M(n) \log n$ and for problems 3 and 4 to be $M(n)(\log n)^{2}$. Moreover, it is shown that each of the four algorithms are really all instances of the same general algorithm. Finally, it is shown how preconditioning or a change of domain will reduce the time for problems 3 and 4 to $M(n)(\log n)$.

title: A Fast Method for Interpolating Preconditioning
abstract: Given n points (x_{i},y_{i}) the best algorithms for finding the unique interpolating polynomial $G(x)$ such that $G(x_{i})=y_{i}$ take $O(n^{2})$ arithmetic operations. If the $(x_{i}$ are known in advance then an algorithm for finding $G(x)$ is presented which takes only $O(n(\log n)^{3})$ steps. Also, it is shown how to precompute certain functions of the x_{i}, in $O(n^{2})$ steps, such that this restricted interpolation algorithm can be easily used. Finally, it is shown that speeding up the general interpolation problem is possible if one can solve a simpler problem, namely to find a polynomial $G(x)$ such that $G(x_{i})=0$ for $1 \leq i \leq j$ and $G(x_{i})=1$ for $j+1 \leq i \leq n$.

title: On the Implementation of Security Measures in Information Systems
abstract: The security of an information system maay be modelled by a matrix whose elements are decision rules and whose row and column indices are users and data items respectively. A set of four functions are used to access this matrix at translation and execution time. Distinguishing between data dependent and data independent decision rules enables one to perform much of the checking of security once at translation time rather than repeatedly at execution time. The model is used to explain security features of several existing systems, and serves as a framework for a proposal for general security system implementation within today's languages and operating systems. Keywords: security, privacy, access control confidentiality, operating systems, access management, data banks, management information systems.

title: Picture Graphs, Grammars, and Parsing
abstract: This paper is concerned with the syntactic description and analysis of pictures when graphs are employed as the primary description formalism. The present state of development, a number of significant open problems, and the advantages and limitations of this approach are discussed under the following three headings: (a) representation of pictures by graphs, (b) graph languages and grammars, and (c) parsing of graphs and pictures. In (a) we investigate transformations from pictures to graphs based on n-ary relations $(n \geq 1)$ that exist among picture components, both at the primitive pattern level and among higher level subpictures; n-ary relations are reduced when $n>2$ or expanded when $n=1$ to binary relations. Several grammatical schemes for generating graph descriptions are then evaluated with respect to their descriptive adequacy, complexity, and practical and theoretical tractability. Syntax-directed analysis of graphss and pictures is treated from two points of view - how to parse efficiently and how to enlist the descriptive mechanism as an aid in the difficult lower level pattern recognition tasks. The latter point is particularly

emphasized with the aim of promoting a more systematic approach to contextual recognition.

title: Subrecursive Programming Languages II: On Program Size
abstract: Programming languages which express programs for all computable (recursive) functions are called universal, those expressing programs only for a subset are called subrecursive programming languages, SPL's.
M. Blum has shown that for certain SPL's any universal programming language (UPL) contains programs which are arbitrarily shorter and nearly as efficient as the shortest SPL program for the same function. We offer new proofs of this theorem to make the relationship. between size and efficiency more revealing and to show that finitely often efficiency is the price of economy of size. From the new proof we derive refinements of the basic theorem. In particular we consider the size-efficiency exchange for the task of computing constants, and derive a measure of the relative expressive power of SPL's. The results are illustrated with some new programming language models.

title: Subrecursive Programming Language III, The Multiple Recursive Functions, $\Re^{n}$
abstract: The characterization of program structure is an elusive aspect of the theory of programming languages. Contingent on such a characterization is an interesting study of the trade-off relationships between program structure and efficiency, between structure and intelligibility, between structure and size, and so forth. One promising definition of program structure is suggested by the studies of the structure of recursion schemata pursued by logicians in the 1930's. In this paper we carry over some of these ideas to programming and present new computer-oriented definitions of certain well-known classes of recursive functions, namely the multiple recursive,$\Re^{n}$, function of Peter. The treatment will facilitate discussions of ultra-complex functions when the need arises. Surprisingly, the need to discuss them does arise frequently at least for doubly recursive function when teaching results about primitive recursive functions and the various languages for computing them. Students want examples of non-primitive recursive functions and computations. Theoreticians also want simple examples of functions which have high structural as well as computational complexity. $\Re^{2}$ functions and the languages given here serve these purposes.

title: Subrecursive Program Schemata I and III. Undecidable Equivalence Problems and II. Decidable EquivalenceProblems
abstract: The study of program schemata and the study of subrecursive programming languages are both concerned with limiting program structure in order to permit a more complete analysis of algorithms while retaining sufficiently rich computing power to allow interesting algorithms. In this paper we combine these approaches by defining classes of subrecursive program schemata and investigating their equivalence problems. Since the languages are all subrecursive, any scheme written in any one of them must halt (as long as we assume the basic functions and predicates are all total). Hence equivalence of schemes is the first question of interest we can ask about these languages. We consider schematic versions of various subrecursive programming languages similar to the Loop language. We distinguish between Pre-Loop and Post-Loop languages on the basis of whether the exit condition in an iteration loop is tested before iteration, as in Algol (Pre-), or after iteration, as in FORTRAN (Post-). We show that at the program level all these languages have the same computing power (the primitive recursive functions) and all have unsolvable equivalence problems (of arithmetic degree Π^{0}_{1}). But at the level of schemes, Pre-Loop has an unsolvable equivalence problem, while at least one formulation of Post-Loop has a solvable equivalence problem. If L is a programming language or scheme language, then we denote by E(L) the equivalence problem in L. The basic languages considered are: Loop ($\equiv$ Pre-Loop) - Loop language for primitive recursive functions. Post-Loop - Post-Loop language for primitive recursive functions. Loop$_{\Diamond}$ - Loop language with restricted

conditionals. L [D, ()] - Loop schemata over D with identity. L$_{\Diamond}$ [D, ()] - Loop schemata with conditionals. PL [D, ()] - Post-Loop schemata over D. PL$_{\Diamond}$ [D, ()] - Post-Loop schemata with conditionals. P - Program (flowchart) schemata. P$_{d}$ - Program schemata with DO-statements. In contrast to (pure) Loop schemata studied previously by the first author, some of these languages contain the identity function so that a pure data transfer, $X \leftarrow Y$, is possible. Moreover, the equivalence algorithms given here are for the special case of linear schemes (to be defined below) with monadic function variables. Linear schemes are designated by placing L before the name of the more general class, thus LL for linear Loop, LPL for linear Post-Loop, etc. In all schemes considered here the functions are monadic, so no special designation of function rank is provided. It is well known that E(P) is recursively unsolvable and E(P) $\in \Pi^{0}_{2}$. We show that E(Loop), E(Post-Loop), E(L$_{\Diamond}$) (both with and without the pure data transfer), and E(L) are recursively unsolvable, while E(LPL) is recursively solvable. The extension of the equivalence algorithm for LPL to polyadic functions appears at present to be a tedious but straightforward modification to the monadic algorithm. We are hopeful that a simpler and more generally applicable technique will emerge for demonstrating solvability or unsolvability of this class of equivalence problems. The algorithm and proofs given here are but a crude first step in delimiting this problem.

title: Algorithms for Shortest Paths
abstract: New algorithms are presented for the general all pairs and single source shortest path problems and for the single source problem restricted to nonnegative arc weights. The new algorithms are faster on sparse networks than algorithms previously known. In addition, new results are presented on the behavior of well-known algorithms, two of which have exponential running times under surprisingly innocuous conditions.

title: Program Schemes with Pushdown Stores
abstract: We attempt to characterize classes of schemes allowing pushdown stores, building on an earlier work by Constable and Gries [1]. We study the effect (on the computational power) of aloowing one, two, or more pushdown stores, both with and without the ability to detect when a pds is empty. A main result is that the use of using one pds is empty. A main result is that the use of using one pds is computationally equivalent to allowing recursive functions. We also study the effect of adding the ability to do integer arithmetic, and multi-dimensional arrays. Keywords: Program schemes, schemata, pushdown stores, stacks, recursion, programming languages.

title: The Efficient Calculation of Powers of Polynomials
abstract: Suppose we are given a polynomial $P(x_{1},\ldots,x_{r})$ in $r \geq 1$ variables, let m bound the degree of P in all variables $x_{i}, l \leq i \leq r$, and we wish to raise P to the n^{th} power, $n>1$. In a recent paper which compared the iterative versus the binary method it was shown that their respective computing times were $O(m^{2r}n^{r+1})$ versus $O((mn)^{2r})$ when using single precision arithmetic. In this paper a new algorithm is given whose computing time is shown to be $O((mn)^{r+1})$. Also if we allow for polynomials with multiprecision integer coefficients, the new algorithm presented here will be faster by a factor of $m^{r-1}n^{r}$ over the binary method and faster by a factor of m^{r-1} over the iterative method. Extensive empirical studies of all three methods show that this new algorithm will be superior for polynomials of even relatively small degree, thus guaranteeing a practical as well as a useful result.

title: The Application of Symbolic Mathematics to a Singular Perturbation Problem
abstract: A basic technique for the numerical solution of ordinary differential equations is to express them as a singular perturbation problem. However, computational studies indicate that the resultant matrix equations which must be solved are often highly ill-conditioned. In this paper a particular singular perturbation problem which was shown to be ill-conditioned using 8 numerical methods is solved by symbolic techniques. These techniques lead both to an analytic proof of the solution plus to the precise knowledge of the asymptotic behavior of the solution vector as it converges. The difficulties encountered in solving the problem symbolically are discussed. Then several conclusions are drawn about the merits of a symbolic versus a numeric approach when applied to the solution of linear systems. Finally some advice and warnings to both the user and the designer of symbol manipulation systems are given concerning their goals and expectations when large matrix equations are to be solved.

title: A Polynomial Bound on the Complexity of the Davis-PutnamAlgorithm Applied to Symmetrizable Propositions
abstract: The problem considered is the relation of minimal computation space to minimal computation time; more specifically, it is desired to determine the time complexity of the tautology problem for propositional logic; the space complexity is known to be linear. This is of special interest in view of Stephen Cook's p-reducibility theorem (May, 1971 ACM Symposium). Algorithms considered are the analytic tableau method, which appears to be inalterably exponential in space and time, and the Davis-Putnam algorithm, part of a resolution procedure introduced in JACM in 1960. Although the algorithm as stated has been shown to be exponential, the known examples are disposed of by (1) locally optimizing the choice of elimination variable and (2) using the subsumption rule (absorption rule), which asserts that if any clause is identical to a subclause of another

clause, the larger clause may be deleted. An algebraic notation is developed which makes it clear that Davis and Putnam's Rules 1 and 2 are special cases of Rule 3 plus local optimization and subsumption. The algebraic notation consists of using vectors to represent clauses; the i^{th} element of the vector is equal to +, -, 0, or 1, according as the i^{th} variable occurs positively, negatively, or not at all. This notation is used in an APL computer program; by using 01,10,00, and 11 to represent +, -, 0, and 1, the program can be written entirely in terms of APL logical operators on arrays, with loops needed only because of size limitations, at a considerable savings in time and space compared to a list representation of the formula, for up to about twenty variables. The proof in brief of the polynomial special-case bound: Call a DNF formula ``reduced'' if the subsumption rule will delete no clauses; call it ``symmetric'' if it is invariant (as a set of clauses) under interchange of variable names. For any clause R, let R^{+} be the number of positive literals in R and $R{-}$ the number of negated literals. Call (R^{+},R^{-}) the (clause-)type of R. A symmetric formula A then satisfies the property that if (R^{+},R^{-}) is the type of some clause in A, then every clause of type (R^{+},R^{-}) is also a clause of A. An algebra of clause-types is developed; it is easily shown that if $r=(R^{+},R^{-})$ and $s=(S^{+},S^{-})$ are unequal types of a reduced symmetric DNF formula (RSDNF), then either $R^{+} greater than S^{+}$ and $R^{-} less than S^{-}$, or $R^{+} less than S^{+}$ and $R^{-} greater than S^{-}$. The former pair is denoted $``r \ogeq s''; \ogeq$ is a strict ordering of clause-types, which is total for RSDNF's. If $r \ogeq s$ and for no p of E is $r \ogeq p \ogeq s$, say r adj s (in E). Denote by PROD(A) the result of one iteration of the Davis-Putnam algorithm with subsumption. Let E be and RSDNF in V variables. The t is a type of PROD(E) if either (1) t is a type of E (with $t^{+} + t^{-} \leq V-1)$, and for no x or y is $(t^{+} + 1, x)$ or $(y, t^{-} + 1)$ a type of E; or (2) $t=(r^{+} -1, s^{-} -1)$, with r adj s in E. It is further shown that if r adj s in PROD(E), then either $r^{+} = s^{+} +1$, or $s^{-} =r^{-} +1$, or $(r^{+} -1, s^{-} -1)$ is not a type of PROD(PROD(E)). A simple combinatorial argument then shows that each type of PROD(PROD(E)) has fewer clauses than some type of PROD(E). The polynomial bound is then immediate, since there are at most $V+1$ types in any RSDNF formula in V variables, and the number of varialbles decreases with each iteration, and there can be at most V iterations. The extension to symmetrizable is trivial.

title: A Model for Adaptive Problem Solving Applied to Natural Language Acquisition
abstract: Adaptive Problem Solving is the application of artificial intelligence learning techniques to practical problems. The approach taken in studying Adaptive Problem Solving is three-fold. First, to develop a model for Adaptive Problem Solving in order to specify the processes involved in computer learning, as well as the interaction between these processes. Second, theoretically well-founded, practical algorithms are developed for each of these learning processes. Third, as an application of this theory, the Natural Language Acquisition Problem is formulated in terms of the adaptive model. The specification of algorithms to perform the learning processes leads to the development of the Bandwidth Heuristic Search, an extension of the heuristic search,

that includes many practical considerations without forfeiting any theoretical capabilities. A modification of this algorithm, the Bandwidth Heuristic Search for MIN/MAX trees is shown to be superior to the alpha-beta minimax process. The model is applied to the Natural Language Acquisition Problem in order to force an encounter with several critical problems involved with computer learning. The Natural Language Acquisition Problem is the problem of providing a robot the adaptive mechanisms sufficient to learn to converse with a human teacher using natural language. The robot first learns the lexicon of the language by correlating the teacher's description of the robot's actions with the robot's internal description. Then the robot infers a grammar that reflects the structure of the teacher's sentences. At this point the robot can begin conversing using a natural language. The linguistic capability of the robot includes the ability to disambiguate lexical and structural ambiguities, and the ability to formulate full sentence replies. After several learning sessions the robot converses in English using nested dependent clauses. This adaptive linguistic system successfully copes with many of the critical problems involved in computer learning and serves as an example of an adaptive program in which the learning, rather than yielding only minor improvements, provides the primary basis for successful performance.

title: Computing Partitions with Applications to the Knapsack Problem
abstract: Given r numbers $s_{1}, \ldots, s_{r}$, algorithms are investigated for finding all possible combinations of these numbers which sum to M. This problem is a particular instance of the 0-1 unidimensional knapsack problem. All of the usual algorithms for this problem are investigated both in terms of asymptotic computing times and storage requirements, as well as average computing times. We develop a technique which improves all of the dynamic programming methods by a square root factor. Using this improvement a variety of new heuristics and improved data structures are incorporated for decreasing the average behavior of these methods. The resulting algorithms are then compared on a wide set of data. It is then shown how these improvements can be applied to various versions of the knapsack problem. Key words and Phrases: partitions, knapsack problem, dynamic programmiing, integer optimization.

title: Program Schemata and Information Flow: A Study of Some Aspects of the Schema Power of Data Structures
abstract: The concept of a program schema, which represents the skeleton of a computer program, is important for its potential and actual applicability to code optimization, to understanding the behavior of programs using various control and data structure features, and to developing a theory of information flow as related to program form and power. In this study tow storage devices, the tape and the queue, are considered, and their effect on the schema power hierarchy explored. The behavior and relative capability of each one of the various types of tapes and queues is discussed in the light of the ways in which information is allowed to move, according to the inherent characteristics of the devices. Main results include the facts that addition of a single tape unit to the simplest schema class P gives no additional power, and that the basic cyclic nature of queues and the persistence of data on tapes are important power determinants. An attempt is made to bridge the gap between schema theory and actual programs not only by studying models of actual storage units but also by allowing an arbitrarily long (but finite) input stream. Such an extension generally upsets the onion-like power inclusions of the finite input hierarchy because of the calculations possible on the implicitly-

input arbitrary integer, which is the number of inout values. The information flow characteristics of the data structures associated with a particular schema class may allow such an arbitrary input to be viewed exactly once, exactly twice, or in general m times, and such distinctions give rise to differences in computational power. Requirements insuring that the interconnection of schemata form a schema with the union of the capabilities of the subschemata are considered. The hierarchy of schemata without the identity assignment is also studied, and it is demonstrated that in the simplest class P and the universal class P_{Ae} no loss of power results from prohibiting identity assignments. Discussion of the as-yet-unsolved problem of the power of the class $P_{(2b,0)}$ and its associated derivatives is presented. A summary of prospects for developing program schema research in several different potentially practical directions concludes the work.

title: Decidable Pairing Functions
abstract: In Chapter I of this paper we show that the usual, textbook pairing functions have decidable first-order theories. This will be done by exhibiting an infinite axiomatization of certain pairing functions which we characterize as ``acyclic except for $\triangle$''. This condition is satisfied by the usual pairing functions. We then use a technique of Ehrenfeucht and Fraisse to show that the decision problem for such a pairing function is effectively reduced to the decision problem for the function restricted to $\triangle$. In contrast to the decidability of the first-order theories of certain pairing functions, we show that the weak second-order and monadic second-order theories of these pairing functions are undecidable. In Chapter II we show how to extend the first-order Ehrenfeucht game to a second-order game. Using this extended game, we show that the monadic second-order theory of an equivalence relation is decidable. Some of the results of Chapter I were announced in [16].

title: Proposals for a Dynamic Library
abstract: The current library environment is first examined, and an attempt is made to explain why the standard approaches to the library problem have been less productive than had been anticipated. A new design is then introduced for modern library operations based on a two-fold strategy: on the input side, the widest possible utilization should be made of cooperative and shared operations, whereas dynamic, user-controlled procedures should be used for the subsequent internal processes. The dynamic environment applies in particular to the maintenance of the indexing vocabulary, the organization of the stored information files,

the performance of search and retrieval operations, and the control of the library collection necessitated by document growth and retirement. Some experimental results are included as an illustration for the proposed dynamic operations.

title: Duality Applied to the Complexity of Matrix Multiplication and Other Bilinear Forms
abstract: The paper considers the complexity of bilinear forms in a noncommutative ring. The dual of a computation is defined and applied to matrix multiplication and other bilinear forms. It is shown that the dual of an optimal computation gives an optimal computation for a dual problem. An nxm by mxp matrix product is shown to be the dual of an nxp by pxm or an mxn by nxp matrix product implyiing that each of the matrix products requires the same number of multiplications to compute. Finally an algorithm for computing a single bilinear form over a noncommutaative ring with a minimum number of multiplications is derived by considering a dual problem.

title: Describing an Algorithm by Hopcroft
abstract: We give an algorithm, its correctness proof, and its proof of execution time bound, for finding the sets of equivalent states in a deterministic finite state automaton. The time bound is $K\cdotm\cdot\n\ cdot\\log n$ where K is a constant, m the number of input symbols, and n the number of states. Hopcroft [3] has already published such an algorithm. The main reason for this paper is to illustrate the use of communicating an algorithm to others using a structured, top-down approach. We have also been able to improve on Hopcroft's algorithm by reducing the size of the algorithm and correspondingly complicating the proof of the running time bound.

title: Testing Flow Graph Reducibility
abstract: Many problems in program optimizationn have been solved by applying a technique called interval analysis to the flow graph of the program. A flow graph which is susceptible to this type of analysis is called reducible. This paper describes an algorithm for testing whether a flow graph is reducible. The algorithm uses depth-first search to reveal the structure of the flow graph and a good method for computing disjoint set unions to determine reducibility from the search information. When the algorithm is implemented on a random access computer, it requires $O(E \log^{*} E)$ time to analyze a graph with E edges, where $\log^{*} x=\min\{i|\log^{i}x \leq 1\}$. The time bound compares favorably with the $O(E \log E)$ bound of a previously known algorithm.

title: On the Substitution of Polynomial Forms
abstract: The problem of devising efficient algorithms for computing $Q(x_{1},\ldots,x_{r-1},P(x_{1},\ldots,x_{r-1}))$ where P and Q are multivariate polynomials is considered. It is shown that for polynomials which

are completely dense an algorithm based upon evaluation and interpolation is more efficient than Horner's method. Then various characterizations for sparse polynomials are made and the subsequent methods are re-analyzed. In conclusion, a test is devised which takes only linear time to compute and by which a decision can automatically be made concerning whether to use a substitution algorithm which exploits sparsity or one which assumes relatively dense inputs. This choice yields the method which takes the fewest arithmetic operations.

title: Generalized Bottom-Up Parsing
abstract: In this thesis we present a decision procedure for testing the correctness of a broad class of bottom-up parsing machines. Motivated by the work of Colmerauer and Williams, we allow our parsers to find any simple phrase (not necessarily the leftmost) in the input string. Such a parser can be implemented on an automaton using two puchdown stores and can in fact produce a complete parse for an input string in linear time with respect to the length of the input. Certain restrictions are necessary in order for the method to work, but nevertheless it is sufficiently general to handle most existing classes of parsers. Moreover, the adjustment of certain parameters to this decision procedure gives rise in a natural way to such classes of grammars as the LR(k) class of Knuth, the BRC class of Floyd and the BCP class of Williams. Further adjustment of these parameters suggests other, more general, classes of parsable grammars which we investigate here for the first time. Among these new classes of grammars is one first suggested by Knuth and given the name LR(k,t). This class is a generalization of the LR(k) method and intuitively is that class of grammar for which it is possible, in any sentential form, to find one of the t leftmost simple phrases given only that portion of the string to the left of the phrase and the first k characters to its right. We give an exact construction for parsers of this class and present the surprising fact that these grammars can be parsed using a deterministic pushdown automaton. We also investigate a class herein called $LR(k,\infty)$ in which we completely relax the condition that the selected phrase be in any certain location. This latter class, which represents the ultimate left to right bottom-up parser, is shown to be too general to have “nice” decidability properties. A final class of grammars investigated is designated FPFAP(k), that is, the class of grammars which are parsable in a left to right fashion by a finite state automaton using k characters of lookahead. This class is shown to lie strictly between the LR(k,t) and $LR(k,\infty)$ classes. We conclude by demonstrating the relationship between these and other classes of grammars, not only from the point of view of the grammars themselves, but also with regard to the classes of languages induced by the grammars.

title: The LBA Problem and its Importance in the Theory of Computing
abstract: In this paper we study the classic problem of determining whether the deterministic and non-deterministic context-sensitive languages are the same or, equivalently, whether the languages accepted by deterministic and non-deterministic linearly bounded automata are the same. We show that this problem is equivalent to several other natural problems in the theory of computing and that the techniques used on the LDA problem have several other applications in complexity theory. For example, we show that there exists a hardest-tape recognizable non-deterministic context-sensitive language L_{1}, such that L_{1} is a deterministic context-sensitive language if and only if the deterministic and non-deterministic context-sensitive languages are the same. We show furthermore, that many decision problems about sets described by regular expressions are instances of these tape-hardest recognizable context-sensitive languages. Thus, it follows that non-determinism in Turing machine computations (using at least linear tape) can not save memory over deterministic Turing machine computations if and only if the equivalence of regular expressions can be decided by a deterministic linearly bounded automaton. It also follows that the equivalence of regular expressions can be decided by a non-deterministic linearly bounded automaton if and only if the family of context-sensitive languages is closed under complementation.

title: Classes of Functions and Feasibility Conditions in Nonlinear Complimentarity Problems
abstract: Given a mapping F from real Euclidean n-space into itself, we investigate the connection between various known classes of functions and the nonlinear complementarity problem: Find and $x^{*} \geq 0$ such that $ F x^{*} \geq 0$ and is orthogonal to x^{*}. In particular, we study the extent to which the existence of a $u \geq 0$ with $F $u \geq 0$ (feasible point) implies the existence of a solution to the nonlinear complementarity problem, and extend, to nonlinear mappings, known results in the linear complementarity problem on P-matrices, diagonally dominant matrices with nonnegative diagonal elements, matrices with off-diagonal non-positive entries, and positive semidefinite matrices.

title: On the Problem of Finding Natural Computational Complexity Measures
abstract: To develop an abstract theory which deals with the quantitative aspects of computing we need a deeper understanding of how to define “natural” computational complexity measures axiomatically. To this end, this paper summarizess the principal properties which hold for some natural complexity measures but not for all measures and which have been proposed as desirable properties of natural measuress. The paper discusses the nature of these properties, studies their interrelations and their possible values towards defining natural computational complexity measures. A number off open problems are discussed and directions for further research are suggested.

title: Gaussian Elimination with Pivoting is Optimal
abstract: V. Strassen discovered that two matrices of order 2 could be multiplied using 7 multiplications and 18 additions of numberss and has shown that two matrices of order n could be multiplied in less than $4 \cdot 7 n^{\log_{2}7}$ operations, an operation being defined as a multiplication, division, subtraction or addition. Also he has shown that the classical Gaussian elimination is not optimal by giving an algorithm to compute the inverse of a nonsingular matrix with certain principal submatrices nonsingular in less than $5 \cdot 64 n^{\log_{2}7}$ operations. In other words, Strassen’s algorithm provides no room for pivoting. J. Bunch and J. Hopcroft have got rid of the above anomaly and have shown how to obtain the triangular

factorization of a permutation of a nonsingular matrix in less than $2 \cdot 44 n^{\log_{2}7}$ operations and the inverse in less than$6 \cdot 83 n^{\log_{2}7}$ operations. In this thesis it is shown, using the results of Strassen and Bunch and Hopcroft, that Gaussian elimination with pivoting is optimal in the sense that the bound for the number of operations required to do Gaussian elimination is the least for "sufficiently large" systems of equations. Also expressions are derived for the various coefficients in the bounds for the various procedures that arise in solving linear systems of equations with the general assumption that two matrices of order u could be multiplied in p multiplications and q additions of numbers.

title: Price Scheduling in a Time-Sharing Queueing System
abstract: This thesis deals with a time-sharing system in which users may join after paying an appropriate toll and are subjected to service and waiting charges. The form of an optimal joining policy that minimizes the expected loss of users who may join the system at some of its queues is derived, and is shown to be a control-limit policy with a single control number for every possible entry queue; a newly arriving user will join the minimal-priority entry queue that is not filled up to its contrl number. Tolls and charges that maximize the average expected revenue of the system, as well as the control numbers, are determined for a round-robin time-sharing system. A multi-entrance foreground-background time-sharing system with random entrance is analyzed and the characteristics of the system, such as expected waiting times and expected number of waiting users in each queue, are given. It is shown that when the entry into this system is based on tolls and charges, there exists a set of prices (and associated control numbers) that maximizes the discounted expected revenues of the system.

title: On Simple Goedel Numberings and Translations
abstract: In this paper we consider Goedel numberings (viewed as simple models for programming languages) into which all other Goedel numberings can be translated very easily. Several such classes of Goedel numberings are defined and their properties are investigated. We also compare these classes of Goedel numberings to optimal Goedel numberings and show that translation into optimal Goedel numberings can be computationally arbitrarily complex.

title: On Computing the Determinant of Matrices with Polynomial Entries
abstract: We consider the problem of computing the determinant of a matrix of polynomials. Four algorithms are compared: expansion by minors, Gaussian elimination over the integers, a method based on evaluation and interpolation, and a procedure which computes the characteristic polynomial of the matrix. Each method is analyzed with respect to its computing time and storage requirements using several models for polynomial growth. The results show which method is preferable for a given computational model. In addition to these asymptotic results, the analysis is exactly done for certain especially small, yet practical and important cases.
Key Words: determinants, matrix of polynomials, Gaussian elimination, expansion by minors, characteristic

polynomial.

title: Theory of Indexing and Classification
abstract: Given a written text in natural language, it is convenient to represent the information content of the text by one or more entities, variously known as concepts, keywords, or terms. It is desired to choose "good" terms which collectively reflect the information content as accurately as possible. A characterization is given of discriminating (good) and non-discriminating (bad) terms, based on the document frequencies of occurrence and the distribution of frequencies of the terms in the documents (texts) of a given document collection. Based on this characterization, reasons are presented for the success and/or the failure of some well-known indexing methods, namely thesaurus construction, "weighting" of the rare terms, and the deletion of non-discriminating terms. A method, which converts non-discriminating terms to discriminating terms is described. Experiments are performed to show that the new method is of practical use. In order to improve the content analysis (indexing) further, term classes are constructed using a process known as pseudoclassification. It is shown that the to construct term classes through discriminating terms. Experiments using the new method are performed on two document collections in medicine and aerodynamics. For both collections, the new method yields substantial improvements over the method of the deletion of non-discriminating terms. In Chapter III, the idea of a term class is formalized and generalized. Techniques from the theory of algorithms are used to examine the computational complexity of certain useful methods for the automatic construction of term classes. It is shown that any algorithm which maximizes the number of relevant documents that are retrieved (recall) and the number of irrelevant documents that are rejected (precision) under some pre-assigned term classes is polynomial complete (likely to take exponential amount of computer time). Four heuristic methods which decrease the computaational time for the automatic construction of term classes using a "pseudo-classification" process are presented. Experiments with these methods and their variations produce surprisingly good results. Chapter IV deals with the clustering of documents. A new clustering method which makes use of the query formulations previously processed by the system is presented. The proposed method clusters the requests in the form of a tree. From that tree, a corresponding tree of documents is constructed. The resulting clusters have the following useful properties. (1) The clusters are independent of the order in which the documents are processed. (2) Overlapping of clusters is allowed in that documents may appear in more than one class or cluster (3) Not all the documents need to be clustered. The new clustering method is then compared with other automatic classification procedures, namely the Single-Link Method, Dattola's Method, Rocchio's Method and Bonner's Method with repect to systems effectiveness, systems efficiency, and computer time required for clustering. Both theoretical and experimental results seem to indicate that the new method is superior to the olded methods. Chapter V summarizes the resultss obtained in this thesis and indicates possible future research areas. Many of the more tedious or difficult proofs in different parts of the thesis are included in Appendices I, II, and III.

title: On the Time and Tape Complexity of Languages
abstract: We investigate the following: (1) the relationship between the classes of languages accepted by deterministic and nondeterministic polynomial time bounded Turing machines; (2) the relationship between the classes of languages accepted by deterministic and nondeterministic linear bounded automata;

(3) sufficient conditions for undecidability of linguistic predicates; and (4) the time and space complexity of several predicates on the regular sets. We show that the set $\{ R | R$ is a $(\cup, ^{.}, *, \caap)$ regular expression and $L(R) = \{0,1\}^*\}$ is not recognizable by any polynomial space bounded Turing machine. We also find conditions which guarantee that any predicate on the regular sets satisfying them is as hard to decide as emptiness or equivalence.

title: On the Relation of Refinement Between Algorithms
abstract: We define a class of tree schemata and a notion of refinement between trees (finite or infinite). These concepts allow us to talk about different “ways to program an algorithm” and the “structure” of an algorithm. We obtain as a special case certain concepts such as “approximation”, “convergence” and “fixed point semantics” recently employed by Scott to describe the semantics of flow diagrams. We concentrate in this paper on relating our concepts to Scott’s.

title: Contribution to the Theory of Indexing
abstract: An attempt is made to characterize the usefulness of terms occurring in stored documents and user queries as a function of their frequency characteristics across the documents of a collection. It is found that the best terms are those having medium frequency in the collection and skewed frequency distributions. Correspondingly, terms exhibiting either very high or very low document frequency are not as useful. To improve the indexing vocabulary, it becomes necessary to group low frequency terms into classes, and to break up high frequency terms by forming phrases. An indexing theory is described based on term frequency considerations, and a new phrase generation method is introduced. The resulting improvements in the indexing vocabulary are evaluated.

title: Functional Schemas with Nested Predicates
abstract: A class of (monadic) functional schemas with nested predicates is defined. It is shown that termination, divergence and freedom problems for these schemas are decidable. It is proved that when the schemas are more general the freedom problem is undecidable. A procedure is given for deleting the identity function from the schema's definition at the cost of increasing k by 1 when k is the maximum depth of nesting. Part of our results extend results of [1] about schemas without nesting. Our algorithm for checking freedom is not a natural extension of theirs. Furthermore, using our algorithm for schemas without nesting yields a much more efficient way of deciding freedom than the algorithm suggested in [1]. Keywords and Phrases: monadic functional schemas, nested predicates, decision problems, equivalence, freedom, polynomial time, DPDA.

title: On the Computational Complexity of Program Schemata
abstract: An ordering called "faster" is defined on the class of iterative program schemata. It is in good accordance with the intuition of "better" applied to program schemata. Many of the commonly used optimization techniques yield "faster" programs in this sense. For Ianov schemata the relation "faster" is decidable, but even on strong equivalence classes the ordering may be very complicated. For iterative program schemata there is a certain kind of speedup. Whereas there is an arbitrary slowdown for programs, slowdown for program schemata is limited.

title: Polynomial and Abstract Subrecursive Classes
abstract: We define polynomial time computable operator. Our definition generalizes Cook's definition to arbitrary function inputs. Polynomial classes are defined in terms of these operators; the properties of these classes are investigated. Honest polynomial classes are generated by running time. They possess a modified Ritchie-Cobham property. A polynomial class is a complexity class if it is honest. Starting from the observation that many results about subrecursive classes hold for all reducibility relations (e.g. primitive recursive in, elementary recursive in), which were studied so far, we define abstract subrecursive reducibility relation. Many results hold for all abstract subrecursive reducibilities.

title: A Theory of Indexing
abstract: THe content analysis, or indexing problem, is fundamental in information storage and retrieval. Several automatic procedures are examined for the assignment of significance values to the terms, or keywords, identifying the documents of a collection. Good and bad index terms are characterized by objective

measures, leading to the conclusion that the best index terms are those with medium document frequency and skewed frequency distributions. A discrimination value model is introduced which makes it possible to construct effective indexing vocabularies by using phrase and thesaurus transformations to modify poor discriminators - those whose document frequency is too high, or too low - into better discriminators, and hence more useful index terms. Test results are included which illustrate the effectiveness of the theory.

title: Programming Language Semantics Using Extensional λ-Calculus Models
abstract: We prove a theorem which provides an intuitive understanding of the meaning of λ-terms in Scott's extensional λ-calculus models. This allows us to use those models for the definition of high-level programming languages. In order to illustrate this we define a programming language which includes blocks and (arbitrary recursive) procedures. Two aspects justify this approach. First of all, the logical properties of those (typeless) λ-calculus models are appealing for a formalization similar to LCF [6] which formalizes typed λ-calculus models. Secondly, not having the type restrictions that LCF imposes allows us to define the semantics of high-level programming languages in the spirit of

"mathematical semantics" [12] (which is usually based on recursively defined domains), thus the semantic nature of syntactic constructs can be exhibited clearly. Keywords: Mathematical semantics, Programming Languages, λ-calculus Models, typed, typeless, extensional, Logic, LCF.

title: An O(nloglogn) On-line Algorithm for the Insert-Exact Min Problem
abstract: Integers within the range 1,...,n are inserted in a set, and on several occasions the minimal element is extracted from the set. We present an algorithm to executee a sequence of O(n) of these instrucitions on-line in time O(nloglogn) on a Random Access Machine. The instruction repertoire can be extended by instructions like allmin(i) (delete all elements not greater than i), extract max, or predecessor (i) (find the largest element less than i), without disturbing the O(loglogn) processing time per item. Whereas the off-line insert-extract min problem is known to be reducible to the on-line union-find problem, we prove that the off-line insert-allmin problem is equivalent to the off-line union-find problem, hence the off-line problems have faster algorithms. As an application we show that our algorithm can be used to process a sequence of O(n) instructions of the types: "split an interval", "unite two adjacent intervals", and "find the interval currently containing element j", on-line in time O(nloglogn). Keywords: set-manipulation, Analysis of Algorithms, binary tree.

title: 2.25 N-Lower Bound on the Combinational Complexity of Boolean Functions
abstract: Consider the combinational complexity L(f) of Boolean functions over the basis $\Omega = \{f|f:\{0,1\}^{2} \rightarrow \{0,1\}\}$. A new Method for proving linear lower bounds of size 2n is presented. Combining it with methods presented in [7] and [9], we establish for a special set of functions $f^{n}:\{0,1\} : 2.25n \leq L(f) \leq 6n$.

title: Independence Results in Computer Science
abstract: In this note we show that instances of problems which appear naturally in computer science cannot be answered in formalized set theory. We show, for example, that some relativized versions of the famous P = NP problem cannot be answered in formalized set theory, that explicit algorithms can be given whose running time is independent of the axioms of set theory, and that one can exhibit a specific context-free grammar G for which it cannot be proven in set theory that $L(G) = \sum^{*}$ or $L(G) \neq \sum^{*}$.

title: Low-Latency Communication over ATM Networks using Active Messages
abstract: Recent developments in communication architectures for parallel machines have made significant progress and reduced the communication overheads and latencies by over an order of magnitude as compared to earlier proposals. This paper examines whether these techniques can carry over to clusters of workstations connected by an ATM network even though clusters use standard operating system software, are equipped with network interfaces optimized for stream communication, do not allow direct protected user-level access to the network, and use networks without reliable transmission or flow control. In a first part, this paper describes the differences in communication characteristics between clusters of workstations built from standard hardware and software components and state-of-the-art multiprocessors. The lack of flow control and of operating system coordination affects the communication layer design significantly and requires larger buffers at each end than on multiprocessors. A second part evaluates a prototype implementation of the low-latency Active Messages communication model on a Sun workstation cluster interconnected by an ATM network. Measurements show application-to-application latencies of about 20 microseconds for small messages which is roughly comparable to the Active Messages implementation on the Thinking Machines CM-5 multiprocessor.

title: Optimal Message Logging Protocols \\ (Preliminary Version)
abstract: Message logging protocols are an integral part of a technique for implementing processes that can recover from crash failures. All message logging protocols require that the state of a recovered process be consistent with the states of the other processes. This consistency requirement is usually expressed in terms of {\em orphan processes\/}, surviving processes whose states are inconsistent with the recovered state of a crashed process. Orphans are either avoided through careful logging or are eliminated through a somewhat complex recovery protocol. We give a specification of the consistency property “no orphan processes”. From this specification, we describe how different existing classes of message logging protocols (namely {\ em optimistic}, {\em pessimistic}, and a class that we call {\em causal}) implement this property. We then propose a set of metrics to evaluate the performance of message logging protocols, and characterize the protocols that are {\em optimal} with respect to these metrics. We give several examples of optimal message logging protocols that can tolerate f overlapping failures and recoveries for a parameter $f: 1 \le f \le n$, and discuss the tradeoffs that arise in the implementation of these protocols.

title: Proving Safety Properties of Hybrid Systems
abstract: We propose a methodology for the specification, verification, and design of hybrid systems. The methodology consists of the computational model of Concrete Phase Transition Systems, the specification language of Hybrid Temporal Logic (HTL), the graphical system description language of Hybrid Automata, and a proof system for verifying that hybrid automata satisfy their HTL specifications. The novelty of the approach lies in the continuous-time logic, which allows specification of both point-based and interval-based properties (i.e., properties which describe changes over an interval) and provides direct references to derivatives of variables, and in the proof system that supports verification of point-based and interval-based properties. The proof rules demonstrate that sound and convenient induction rules can be established for continuous-time logics. The proof rules are illustrated on several examples.

title: Aspects of the Computational Content of Proofs
abstract: In this thesis, we explore three aspects of the computational content of proofs. These are: a computational interpretation of the metatheory of intuitionistic propositional logic, an extension of this approach to intuitionistic predicate logic, and a computational interpretation of classical sequent proofs. We begin with a study of the computational aspects of validity, provability, and completeness for intuitionistic propositional logic. We give a constructive proof of completeness of Kripke models for intuitionistic propositional calculus, such that the computational content of the proof is a form of the tableau algorithm. Since the evidence for provability we construct is actually a term in typed λ-calculus, we can interpret this result as a formal relationship between Kripke semantics and realizability semantics. We also show how a formal proof of the completeness theorem in Nuprl could be used to add the tableau decision procedure for provability to Nuprl's collection of proof techniques via reflection. We then explore how these results could be generalized to the metatheory of intuitionistic predicate logic. To do this, we develop some machinery for representing infinite Kripke models in type theory using co-inductive types. Although provability in intuitionistic predicate logic is undecidable, we can still prove a constructive theorem in the metatheory which has computational content. We also show that using classical logic in part of the proof does not destroy the computational content of the proof. Finally, we examine the computational aspects of classical sequent proofs. We show how the interpretation of nonlocal control operators as the computational content of classical axioms allows us to prove a completeness result for intuitionistic predicate logic with a depth-first-search tableau procedure as the computational content of the proof. Using the nonlocal control operator \cc\ as the the computational interpretation of the classical axiom we define a method for extracting programs from classical sequent proofs in propositional logic. We give a proof-theoretic account of continuations and their behaviour in this context, and prove a number of properties of the extraction.

title: Preserving Privacy in a Network of Mobile Computers
abstract: Even as wireless networks create the potential for access to information from mobile platforms, they pose a problem for privacy. In order to retrieve messages, users must periodically poll the network. The

information that the user must give to the network could potentially be used to track that user. However, the movements of the user can also be used to hide the user's location if the protocols for sending and retrieving messages are carefully designed. In this paper we will describe a set of protocols that we have developed to allow a user with a mobile computer to communicate without compromising privacy.

title: On Global Convergence of A Trust Region and Affine Scaling Methodfor Nonlinearly Constrained Minimization
abstract: A nonlinearly constrained optimization problem can be solved by the exact penalty approach involving nondifferentiable functions $\sum_{i} |c_i(x)|$ and $\sum_{i}\max(0,c_i(x))$. In \cite{Li94a}, a trust region affine scaling approach based on a 2-norm subproblem is proposed for solving a nonlinear l_1 problem. The (quadratic) approximation and the trust region subproblem are defined using affine scaling techniques. Explicit sufficient decrease conditions are proposed to obtain a limit point satisfying complementarity, dual feasibility, and second order optimality. In this paper, we present the global convergence properties of this new approach.

title: Efficient Program Analysis Using Dependence Flow Graphs
abstract: Program analysis plays a major role in advanced compilers, yet traditional approaches to data flow analysis are quite time consuming. Prior techniques for speeding up data flow analysis have either exploited program structure or have used alternate "sparse" dependence representations to avoid performing unnecessary work. No general method exploiting both program structure and sparsity has emerged. We present a new framework for program analysis using dependence flow graphs (DFGs), an intermediate representation derived from dataflow machine graphs. DFGs integrate data and control dependences in a way that supports general and efficient program analysis while avoiding the problems of previous dependence representations. In particular, our approach simultaneously exploits program structure, sparsity of data flow systems, and data structure reuse to speed up analysis. At the heart of our method is a new program decomposition based on identifying single-entry single-exit (SESE) regions of the control flow graph (CFG). We show that finding SESE regions is equivalent to the problem of finding control dependence regions, and

we develop optimal linear-time algorithms for these problems. The nesting relationship of SESE regions is recorded in a data structure called the program structure tree (PST). Since each SESE region is a control flow graph in its own right, we can speed up many CFG algorithms by applying them independently to each SESE region in a divide-and-conquer manner. Additionally, SESE regions can be categorized according to their local structure (e.g. as if-then-else or loop regions), and this local structure may be exploited by applying simple syntactic methods according to the region kind. Hierarchical program structure is used in solving global data flow problems by first solving local problems within progressively larger SESE regions. The global solution is then propagated to enclosed regions in a top-down pass over the PST. Sparsity is exploited within each data flow problem by avoiding propagation of data flow values through SESE regions that do not effect the data flow solution. We show that the sparsity found in common scalar optimizations is captured precisely by dependence flow graphs; the DFG is then viewed as a reusable "basis set" of sparse graphs. Since sparsity is based on SESE regions of the PST, we may exploit structure and sparsity simultaneously. By solving data flow systems using the DFG, we avoid the cost of rediscovering structure and sparsity for each problem instance. In this case, the cost of building the dependence flow graph is amortized over many related data flow problems. Such data structure reuse is essential to realizing the full potential of sparse data flow methods. However, reuse adds the additional burden of maintaining the DFG as the program is transformed during optimization. Using the PST, we derive practical incremental algorithms for updating both the DFG and the PST itself. We demonstrate the value of our approach through measurements taken from an optimizing FORTRAN compiler that uses the program structure tree and dependence flow graph as its internal representation. From our experiments, we conclude that sparse methods hold great potential for speeding up data flow analysis, but that reusing and incrementally updating a sparse representation is the key to realizing this potential.

title: Larchant-RDOSS: a distributed shared persistent memory and its garbage collector
abstract: Larchant-RDOSS is a distributed shared memory that persists on reliable storage across process lifetimes. Memory management is automatic: including consistent caching of data and of locks, collecting objects unreachable from the persistent root, writing reachable objects to disk, and reducing store fragmentation. Memory management is based on a novel garbage collection algorithm, that approximates a global trace by a series of local traces, with no induced I/O or locking traffic, and no synchronization between the collector and the application processes. This results in a simple programming model, and expected minimal added application latency. The algorithm is designed for the most unfavorable environment (uncontrolled programming language, reference by pointers, distributed system, non-coherent shared memory) and should work well also in more favorable settings.

title: Set Constaints and Logic Programming
abstract: Set constraints are inclusion relations between expressions denoting sets of ground terms over a randed alphabet. They are the main ingredient in set-based program analysis[3,4,12,13,17,20,21,22,26]. In this paper we describe a constraint logic programming language CLP(SC) over set constraints in the style of Jaffar and Lassez[15]. The language subsumes ordinary logic programs over an IIerbrand domain. We give an efficient unification algorithm and operational, declarative, and fixpoint semantics. We show how the language can be applied in set-based program analysis by deriving explicitly the monadic approximation of the collecting semantics of IIeintze and Jaffar[12,13].

title: Operating System Support for Mobile Agents
abstract: An “agent” is a process that may migrate through a computer network in order to satisfy requests made by its clients. Agents implement a computational metaphor that is analogous to how most people conduct business in their daily lives: visit a place, use a service (perhaps after some negotiation), and then move on. Thus, for the computer illiterate, agents are an attractive way to describe network-wide computations. Agents are also useful abstractions for programmers who must implement distributed applications. This is because in the agent metaphor, the processor or “place” the computation is performed is not hidden from the programmer, but the communications channels are. Most current research on agents has focused on language design and application issues. The TACOMA project (Tromso And COrnell Moving Agents) has, instead, focused on operating system support for agents and how agents can be used to solve problems traditionally addressed by operating systems. We have implemented prototype systems to support agents using UNIX and using Tcl/Tk on top of Horus. This paper outlines insights and questions based on that experience. We discuss abstractions needed by an operating system to support agents, and discuss some problems that arise in connection with electronic commerce involving agents.

title: COMPILING FOR NUMA PARALLEL MACHINES
abstract: A common feature of many scalable parallel machines is non-uniform memory access (NUMA) --- data access to local memory is much faster than to non-local memories. In addition, when a number of remote accesses must be made, it is usually more efficient to use block transfers of data rather than to use many small messages. Almost every modern processor is designed with a memory hierarchy organized into several levels -- each smaller and faster than the level below. In general, the effective use of parallel machines requires careful attention to the following issues: (1) exposing and exploiting parallelism; (2) accessing local memory instead of remote memory; (3) using block transfers for remote accesses; (4) reusing data in the cache; and (5) load balancing. We have built a system called {\em Pnuma} for programming NUMA machines. We make the following contributions: First, we propose a parallelization scheme for both parallelism and data locality. Second, we develop a framework based on {\em non-singular} matrices and integer lattice theory for the systematic development of loop transformations. Program transformations, such as loop restructuring,

are critical to achieving high performance. The framework can be used in parallelizing compilers for both coarse-grain and fine-grain parallel architectures. We have implemented a loop restructuring toolkit called {\em Lambda} based on this framework. Third, using this loop transformation framework, we develop algorithms for improving memory locality. The memory locality algorithm restructures loop nests to expose opportunities for parallel execution and for block transfers, while keeping data accesses local wherever possible. Fourth, for cache locality, we introduce a new simple cache model based on {\em reuse distances\/}, which is more precise than the existing {\em reuse vector space} model. We develop a new loop transformation technique that optimizes directly on reuse distances, so that no exhaustive search is necessary. Fifth, we use our loop transformation framework to improve parallelism as well. We develop a unified algorithm for parallelism, memory locality and cache locality. System evaluations have been conducted on a multiprocessor machine without cache (BBN GP1000), a uniprocessor workstation with cache (HP 9000/720) and a multiprocessor machine with caches (KSR1), using programs from linear algebra, NASA benchmarks and SIMPLE hydrodynamics benchmark.

title: An Affine Scaling Algorithm for Minimizing Total Variation in ImageEnhancement
abstract: A computational algorithm is proposed for image enhancement based on total variation minimization with constraints. This constrained minimization problem is introduced by Rudin et al \ cite{osher1,osher3,osher2} to enhance blurred and noisy images. Our computational algorithm solves the constrained minimization problem directly by adapting the affine scaling method for the unconstrained l_1 problem \cite{CL89}. The resulting computational scheme, when viewed as an image enhancement process, has the feature that it can be used in an interactive manner in situations where knowledge of the noise level is either unavailable or unreliable. This computational algorithm can be implemented with a conjugate gradient method. It is further demonstrated that the iterative enhancement process is efficient.

title: Completeness Results for Recursive Data Bases
abstract: We consider infinite recursive (i.e., computable) relational data bases. Since the set of computable queries on such data bases is not closed under even simple relational operations, one must either make do with a very modest class of queries or considerably restrict the class of allowed data bases. We define two query languages, one for each of these possibilities, and prove their completeness. The first is the language of quantifier-free first-order logic, which is shown to be complete for the non-restricted case. The second is an appropriately modified version of Chandra and Harel's language QL, which is proved complete for the case of ``highly symmetric" data bases, i.e., ones whose set of automorphisms is of finite index for each tuple-width. We also address the related notion of BP-completeness.

title: GMRES vs. ideal GMRES
abstract: \begin{abstract} \noindent The GMRES algorithm minimizes $\norm{p(A)b}$ over polynomials p

of degree n normalized at $z=0$. The ideal GMRES problem is obtained if one considers minimization of $\norm{p(A)}$ instead. The ideal problem forms an upper bound for the worst-case true problem, where the GMRES norm $\norm{p_b(A)b}$ is maximized over b. In work not yet published, Faber, Joubert, Knill and Manteuffel have shown that this upper bound need not be attained, constructing a 4×4 example in which the ratio of the true to ideal GMRES norms is 0.9999. Here, we present a simpler 4×4 example in which the ratio approaches zero when a certain parameter tends to zero. The same example also leads to the same conclusion for Arnoldi vs. ideal Arnoldi norms. \end{abstract}

title: Complete Orthogonal Decomposition for Weighted Least Squares
abstract: Consider a full-rank weighted least-squares problem in which the weight matrix is highly ill-conditioned. Because of the ill-conditioning, standard methods for solving least-squares problems, QR factorization and the nullspace method for example, break down. G. W. Stewart established a norm bound for such a system of equations, indicating that it may be possible to find an algorithm that gives an accurate solution. S. A. Vavasis proposed a new definition of stability that is based on this result. He also proposed the NSH algorithm for solving this least-squares problem and showed that it satisfies the new definition of stability. This paper describes a complete orthogonal decomposition algorithm to solve this problem and shows that it is also stable. This new algorithm is simpler and more efficient than the NSH method.

title: Efficient Message Passing Interface (MPI) for Parallel Computing onClusters of Workstations
abstract: Parallel computing on clusters of workstations and personal computers has very high potential, since it leverages existing hardware and software. Parallel programming environments offer the user a convenient way to express parallel computation and communication. In fact, recently, a Message Passing Interface (MPI) has been proposed as an industrial standard for writing "portable" message-passing parallel programs. The communication part of MPI consists of the usual point-to-point communication as well as collective communication. However, existing implementations of programming environments for clusters are built on top of a point-to-point communication layer (send and receive) over local area networks (LANs) and, as a result, suffer from poor performance in the collective communication part. In this paper, we present an efficient design and implementation of the collective communication part in MPI that is optimized for clusters of workstations. Our system consists of two main components: the MPI-CCL layer that includes the collective communication functionality of MPI and a User-level Reliable Transport Protocol (URTP) that interfaces with the LAN Data-link layer and leverages the fact that the LAN is a broadcast medium. Our system is integrated with the operating system via an efficient kernel extension mechanism that we developed. The kernel extension significantly improves the performance of our implementation as it can handle part of the communication overhead without involving user space. We have implemented our system on a collection of IBM RS/6000 workstations connected via a 10Mbit Ethernet LAN. Our performance measurements are taken from real scientific applications that run in a parallel mode by means of the MPI. The hypothesis behind our design is that system's performance will be bounded by interactions between the kernel and user space rather than by the bandwidth delivered by the LAN Data-Link Layer. Our results indicate that the performance of our MPI Broadcast (on top of Ethernet) is about twice as fast as a recently published software implementation of broadcast on top of ATM.

title: Rational Spaces and Set Constraints
abstract: Set constraints are inclusions between expressions denoting sets of ground terms. They have been used extensively in program analysis and type inference. In this paper we investigate the topological structure of the spaces of solutions to systems of set constraints. We identify a family of topological spaces called {\em rational spaces}, which formalize the notion of a topological space with a regular or self-similar structure, such as the Cantor discontinuum or the space of runs of a finite automaton. We develop the basic theory of rational spaces and derive generalizations and proofs from topological principles of some results in the literature on set constraints.

title: Data Types for Very High Level Programming Languages
abstract: Very high level programming languages (higher than PL/I, Algol 60, etc.) attempt to free the programmer from providing details and let him concentrate on the algorithm for the problem at hand. The importance of very high level programming languages is further emphasized by decreasing machine costs, increased programming costs and the desire to have programs that are well structured, easy to understand and prove correct. Very high level languages provide powerful control structures and data structures that allow the problem to be specified in a natural manner. In this dissertation, we propose several ways of raising the level of a language. The different types of for iteration statements are consolidated into one general for statement. This, along with a new type, the domain of an array, provides us with an easy way of processing arrays; nested iteration statements are no longer necessary. The syntactic list and array generators and the concept of overloading make programming more flexible. The current notion that a data type is a set of values together with basic operations on that set leads us to conclude that formal parameter types need not be explicitly stated. Given a formal parameter X with operations $z_{1}, z_{2},\ldots, z_{n}$ being performed on it within the procedure, one should be able to supply, as an actual parameter in a call, a variable of any type that has the operations $z_{1}, z_{2},\ldots, z_{n}$ defined on it. For example, this concept allows us to write one procedure that finds the maximum value of the elements of an array of any dimension and any element or index type. Grids are arrays that can have any shape. Grid elements need not be contiguous i.e. grids can have holes in them. For example, grids can be trapezoidal, parabolic, rectangular with a hole or pyramid-like. Programs written using grids are more general than those written using arrays and/or functions to simulate non-array shapes. To alter an existing program to work for another grid shape one need only modify the grid declaration suitably, leaving the rest of the program intact. Programs are smaller, semantically clearer and have a more natural problem representation. Grids may be used to represent sparse matrices. Data security is achieved by allowing parts of grids pass as parameters to be readd only or completely masked out. Grids have been implemented as an extension to Fortran. Using Pascal as the base language, we show by series of examples from numerical analysis, data processing, engineering etc., how the above concepts raise the level of a programming language and how they blend together naturally and systematically. Efficient ways of implementing them are also discussed.

title: Effective Automatic Indexing Using Single Terms, Term Phrases and Thesaurus Class Assignments
abstract: In a retrieval environment, indexing is the task which consists in the assignment to stored records and incoming information requests of content identifiers capable of representing record or query content. It is known that effective content identifiers (index terms) must exhibit the correct level of specificity in a given collection environment. Terms that are too broad must be rendered specific by being utilized as term phrases, while narrow terms must be broadened by supplying synonymous or related terms normally extracted from a thesaurus. Formal proofs are given in the present study of the retrieval effectiveness of indexing policies using single terms, term phrases and thesaurus class assignments for puposes of content representation. Keywords and Phrases: automatic information retrieval, automatic indexing, content analysis, term phrases, thesaurus classes, term addition, term deletion, retrieval evaluation, recall and precision.

title: A New Modular Interpolation Algorithm for Factoring Multivariate Polynomials
abstract: In this paper, we present a technique that uses a new interpolation scheme to reconstruct a multivariate polynomial factorization from a number of univariate factorizations. Whereas other interpolation algorithms for polynomial factorization depend on various extensions of the Hilbert irreducibility theorem, our approach is the first to depend only upon the classical formulation. The key to our technique is the interpolation scheme for multivalued black boxes originally developed by Ar et. al. [1]. We feel that this combination of the classical Hilbert irreducibility theorem and multivalued black boxes provides a particularly simple and intuitive approach to polynomial factorization.

title: Mesh Generation With Provable Quality Bounds
abstract: We consider the problem of generating a triangulation of provable quality for two and three dimensional polyhedral regions. That is, we seek a triangulation, allowing additional vertices called Steiner points, such that the triangular or tetrahedral elements have a bound on their shape. In three dimensions we also seek an upper bound on the number of tetrahedra in the triangulation. These triangulation algorithms find application in mesh generation for finite element methods. The polyhedral region must be bounded and well defined, but may have holes of arbitrary complexity. In three dimensions, we assume there are no restrictions on where we may place Steiner points. Our triangulation is optimal in the following two senses. First, our triangulation achieves the best possible aspect ratio up to a constant factor, which is our bound on element shape. Second, for any other triangulation of the same region into m triangles with bounded aspect ratio, our triangulation has size $n = O(m)$. Such a triangulation is desired as an initial mesh for a finite element mesh refinement algorithm. Previous three dimensional triangulation schemes either worked only on a restricted class of input, or did not guarantee well-shaped tetrahedra, or were not able to bound the output size. We build on some of the ideas presented in previous work by Bern, Eppstein and Gilbert, who have shown how to triangulate a two dimensional polyhedral region with holes, with similar quality and optimality bounds. In two dimensions, we assume the restriction that we may introduce Steiner points on the polygon's interior, but not on its boundary. Of all triangulations satisfying this restriction, our triangulation has the maximum minimum angle, up to a constant factor. This is the first known algorithm

for this problem with provably optimal element shape. The algorithm solves several subproblems of mesh generation.

title: Process Membership in Asynchronous Environments
abstract: The development of reliable distributed software is simplified by the ability to assume a fail-stop failure model. We discuss the emulation of such a model in an asynchronous distributed environment. The solution we propose, called Strong-GMP, can be supported through a highly efficient protocol, and has been implemented as part of a distributed systems software project at Cornell University. Here, we focus on the precise definition of the problem, the protocol, correctness proofs and an analysis of costs. Keywords: Asynchronous computation; Fault detection; Process membership; Fault tolerance; Process group.

title: Temporal Proof Methodologies for Timed Transition Systems
abstract: We extend the specification language of temporal logic, the corresponding verification framework, and the underlying computational model to deal with real-time properties of reactive systems. The abstract notion of timed transition systems generalizes traditional transition systems conservatively: qualitative fairness requirements are replaced (and superseded) by quantitative lower-bound and upper-bound timing constraints on transitions. This framework can model real-time systems that communicate either through shared variables or by message passing and real-time issues such as timeouts, process priorities (interrupts), and process scheduling. We exhibit two styles for the specification of real-time systems. While the first approach uses time-bounded versions of the temporal operators, the second approach allows explicit references to time through a special clock variable. Corresponding to the two styles of specification, we present and compare two different proof methodologies for the verification of timing requirements that are expressed in these styles. For the bounded-operator style, we provide a set of proof rules for establishing bounded-invariance and bounded-response properties of timed transition systems. This approach generalizes the standard temporal proof rules for verifying invariance and response properties conservatively. For the explicit-clock style, we exploit the observation that every time-bounded property is a safety property and use the standard temporal proof rules for establishing safety properties.

title: Solving L_{p}-Norm Problems and Applications
abstract: The l_{p} norm discrete estimation problem min$_{x\in\Re^{n}} \Vert b-A^{T} x\Vert^{p}_{p}$ has been solved in many data analysis applications, e.g. geophysical modeling. Recently, a new globally convergent Newton method (called GNCS) has been proposed for solving $l{p}$ problems with 1 $\leq p \leq$ 2 [5]. This method is much faster than the widely used IRLS method when 1 $\leq p \leq$ 1.5 and comparable to it when $p greater than $ 1.5. In this paper, modification is made to the line search prodedure so that the GNCS method is applicable for l_{p} problems with 1 $\leq p less than \infty$. The global convergence results for l_{1} problems are obtained under weaker assumptions than required in [2]. In addition, the usefulness of l_{p} norm solution with 1 $\leq p \leq$ 2 is demonstrated by applying the GNCS algorithm to a synthetic geophysical tomographic inversion problem. Additional numerical results are included to support the efficiency of GNCS. Key Words: linear regression, discrete estimation, tomographic inversion, IRLS, GNCS, linear programming, Newton method. Subject Classification: AMS/MOS: 65H10, 65K05, 65K10.

title: On the Robustness of Herlihy's Hierarchy
abstract: A wait-free hierarchy maps object types to levels in $Z^{+} \cup \{ \infty \}$, and has the following property: if a type T is at level N, and T' is an arbitrary type, then there is a wait-free implementation of an object of type T', for N processes, using only registers and objects of type T. The infinite hierarchy defined by Herlihy is an example of a wait-free hierarchy. A wait-free hierarchy is robust if it has the following property: if T is at level N, and $\cal S$ is a finite set of types belonging to levels N -- 1 or lower, then there is no wait-free implementation of an object of type T, for N processes, using any number and any combination of objects belonging to the types in $\cal S$. Robustness implies that there are no clever ways of combining weak shared objects to obtain stronger ones. Contrary to what many reserchers believe [AGTV92, AR92, Her91a], we prove that Herlihy's hierarchy is not robust. We then define some natural variants of Herlihy's hierarchy, which are also infinite wait-free hierarchies. With the exception of one, which is still open, these are not robust either. We conclude with the open question of whether non-trivial robust wait-free hierarchies exist.

title: Approaches to Passage Retrieval in Full Text Information Systems

abstract: Large collections of full-text documents are now commonly used in automated information retrieval. When the stored document texts are long, the retrieval of complete documents may not be in the users' best interest. In such circumstances, efficient and effective retrieval results may be obtained by using passage retrieval strategies designed to retrieve text excerpts of varying size in response to statements of user interest. New approaches are described in this study for implementing selective passage retrieval systems, and identifying text passages responsive to particular user needs. An automated encyclopedia search system is used to evaluate the usefulness of the proposed methods.

title: A Theorem Proving Based Methodology for Software Verification
abstract: We have developed an effective methodology for using a proof development system to prove properties about functional programs. This methodology includes techniques such as hiding implementation details and using higher order theorems to structure proofs and aid in abstract reasoning. The methodology was discovered and refined while verifying a logic synthesis tool with the Nuprl proof development system. The logic synthesis tool, Pbs, implements the weak division algorithm. Pbs consists of approximately 1000 lines of code implemented in a functional subset of Standard ML. It is a proven and usable implementation of a hardware synthesis tool. The program was verified by embedding the subset of SML in Nuprl and then verifying the correctness of the implementation of Pbs in the Nuprl logic.

title: Virtually-Synchronous Communication Based on a Weak Failure Suspector
abstract: Failure detectors (or, more accurately, Failure Suspectors - FS) appear to be a fundamental service upon which to build fault-tolerant, distributed applications. This paper shows that a FS with very weak semantics (i.e. that delivers failure and recovery information in no specific order) suffices to implement virtually-synchronous communication (VSC) in an asynchronous system subject to process crash failures and network partitions. The VSC paradigm is particularly useful in asynchronous systems and greatly simplifies building fault-tolerant applications that mask failures by replicating processes. We suggest a three-component architecture to implement virtually-synchronous communication : 1) at the lowest level, the FS component; on top of it, 2a) a component that defines new views, and 2b) a component that reliably multicasts messages within a view. The issues covered in this paper also lead to a better understanding of the various membership service semantics proposed in recent literature.

title: Undecidability in Macroeconomics (Preliminary Draft)
abstract: In this paper, we study the difficulty of solving problems in economics. For this purpose, we adopt the notion of undecidability from recursion theory. We show that certain problems in economics are undecidable, i.e., cannot be solved by a Turing Machine, a device that is at least as powerful as any computational device that can be constructed [2]. In particular, we prove that even in finite closed economies subject to a variable initial condition, in which a social planner knows the behavior of every agent in the economy, certain important social planning problems are undecidable. Thus, it may be impossible to make effective policy decisions. Philosophically, this result formally brings into question the Rational Expectations Hypothesis, which assumes that each agent is able to determine what it should do if it wishes to maximize its utility. We show that even when an optimal rational forecast exists for each agent (based on the information currently available to it), agents may lack the ability to make these forecasts. For example, Lucas [7] describes economic models as “mechanical, artificial world(s), populated by ... interacting robots”. Since any mechanical robot can be at most as computationally powerful as a Turing Machine, such economies are vulnerable to the phenomenon of undecidability.

title: On Information Invariants in Robotics
abstract: We consider the problem of determining the information requirements to perform robot tasks, using the concept of information invariants. This paper represents our attempt to characterize a family of

complicated and subtle issues concerned with measuring robot task complexity. We also provide a first approximation to a purely operational theory that addresses a narrow but interesting special case. We discuss several measures for the information complexity of a task: (a) How much internal state should the robot retain? (b)How many cooperating agents are required, and how much communication between them is necessary? (c) How can the robot change (side-effect) the environment in order to record state or sensory information to perform a task? (d) How much information is provided by sensors? and (e) How much computation is required by the robot? We consider how one might develop a kind of "calculus" on (a) - (e) in order to compare the power of sensor systems analytically. To this end, we attempt to develop a notion of information invariants. We develop a theory whereby one sensor can be "reduced" to another (much in the spirit of computation-theoretic reductions), by adding, deleting and reallocating (a) - (e) among collaborating autonomous agents.

title: An Interior Trust Region Approach for Nonlinear Minimization Subject to Bounds
abstract: We propose a new trust region approach for minimizing a nonlinear function subject to simple bounds. By choosing an appropriate quadratic model and scaling matrix at each iteration, we show that it is not necessary to solve a quadratic programming subproblem, with linear inequalities, to obtain an improved step using the trust region idea. Instead, a solution to a trust region subproblem is defined by minimizing a quadratic function subject only to an ellipsoidal constraint. The iterates generated by these methods are always strictly feasible. Our proposed methods reduce to a standard trust region approach for the unconstrained problem when there are no upper or lower bounds on the variables. Global and quadratic convergence of the methods is established; preliminary numerical experiments are reported.

title: Hybrid Automata: An Algorithmic Approach to the Specification and Verification of Hybrid Systems
abstract: We introduce the framework of hybrid automata as a model and specification language for hybrid systems. Hybrid automata can be viewed as a generalization of timed automata, in which the behavior of variables is governed in each state by a set of differential equations. We show that many of the examples considered in the workshop can be defined by hybrid automata. While the reachability problem is undecidable even for very restricted classes of hybrid automata, we present two semidecision procedures for verifying safety properties of piecewise-linear hybrid automata, in which all variables change at constant rates. The two procedures are based, respectively, on minimizing and computing fixpoints on generally infinite state spaces. We show that if the procedures terminate, then they give correct answers. We then demonstrate that for many of the typical workshop examples, the procedures do terminate and thus provide an automatic way for verifying their properties.

title: Parametric Real-Time Reasoning
abstract: Traditional approaches to the algorithmic verification of real-time systems are limited to checking program correctness with respect to concrete timing properties (e.g., "message delivery within 10 milliseconds"). We address the more realistic and more ambitious problem of deriving symbolic constraints on the timing properties required of real-time systems (e.g., "message delivery within the time it takes to execute two assignment statements"). To model this problem, we introduce parametric timed automata - finite-state machines whose transitions are constrained with parametric timing requirements. The emptiness question for parametric timed automata is central to the verification problem. On the negative side, we show that in general this question is undecidable. On the positive side, we provide algorithms for checking the emptiness of restricted classes of parametric timed automata. The practical relevance of these classes is illustrated with several verification examples. There remains a gap between the automata classes for which we know that emptiness is decidable and undecidable, respectively, and this gap is related to various hard and open problems of logic and automata theory.

title: Tradeoffs in Implementing Primary-Backup Protocols
abstract: One way to implement a fault-tolerant service is to replicate the state of a server across a primary server and a set of backup servers. Clients make requests to the primary, which then computes the response, informs the backup of the state change, and then replies to the client. If the primary subsequently fails then a backup takes over as a new primary. Informally, the primary-backup protocol is nonblocking if the primary need not wait for acknowledgements from the backups before responding to the client. While most primary-backup protocols are blocking, we argue that non-blocking protocols can be constructed for most of the process and communication failures that are expected to occur in future communications systems. We then implement and measure the performance of two kinds of nonblocking protocols--one based on point-to-point communication and one based on broadcast--and compare the results with conventional blocking primary-backup protocols.

title: Generating Spectral Method Solvers for Partial Differential Equations
abstract: A major cost in scientific computing is the creation of software that performs the numerical computations. This paper presents preliminary results on research to build a framework for automating the construction of numerical solvers for differential equations. Within this framework, the scientific computing problem is described using a very high level programming language that captures the original differential equations in a natural fashion. A sequence of code "transformers" are used to gradually refine the high level description of the problem into a concrete, executable form. Numerical techniques like the finite

element method, the spectral method and the Crank-Nicolson discretization scheme are encoded in these transformers and once so encoded can be applied to a wide variety of different problems. This framework provides a natural environment for coarse scale parallelization based on relatively abstract properties of the specific equations and methods.

title: Adaptive Error Bracketing for Controlled-Precision Volume Rendering
abstract: We present a new ray tracing approach to volume rendering in which the low-albedo volume rendering integral for each ray is efficiently computed to any prescribed accuracy. By bracketing the emission and absorption functions along each ray with adaptively refined step functions, computation is directed toward large sources of error and continued until a desired accuracy is reached. As a result, coarse approximations can be used in regions that are nearly uniform, of low emission, or of low visibility due to absorption by material closer to the eye. Adaptive refinement for each ray is performed using a hierarchical organization of the volume data; at each step, a part of the ray estimated to contribute large error is refined, and the approximate integral is updated incrementally. Our current implementation operates on regularly-spaced data samples combined with trilinear interpolation; however, the concepts described apply to more general data topologies and reconstruction filters.

title: Fine Motion Planning for Dexterous Manipulation
abstract: This thesis investigates the problem of dexterous manipulation; how can robots affect the world around them by means of their end-effectors? Dexterous manipulation is fundamental to robots operating intelligently and independently in their environments and it is a special motion planning problem. Since the general motion planning problem with uncertainty is NEXP-hard, effort must be directed to defining classes of tasks that are tractable. We consider the reorientation problem: for a given robot hand, an arbitrary object, and a desired orientation with respect to the hand, find an algorithm to synthesize a robust plan for the fingers that accomplishes the desired reorientation. A reorientation algorithm devised for a robot hand should satisfy several properties. First, it must be able to accomplish arbitrarily large rotations. Second, since it must be implemented on a real device, it should involve simple finger motions that can be computed fast. Third, since the application domain is characterized by uncertainties that manifest themselves as imprecisions in calculations and inaccuracies in control, it must exhibit good stability properties. We propose algorithms for the reorientation problem that satisfy these properties. The basic idea is to use some of the robot fingers to constrain the motion of the object and others to generate motion. This results in the idea of finger tracking as a high-level primitive for manipulation. We also propose an algebraic framework for manipulation that is theoretically well-founded and in which it is possible to use systematically and effectively the differential equations describing the interaction between objects in contact. Finally, we describe a simulator for the reorientation of polyhedra by finger tracking.

title: Discontinuity Meshing for Radiosity Image Synthesis
abstract: The simulation of global illumination is one of the most fundamental problems in computer graphics, with applications is a wide variety of areas. This problem studies the light energy transfer between reflective surfaces in an environment. Initially derived from the field of thermal engineering, radiosity has emerged over the past several years as one of the most promising solution methods. Despite having produced some of the most realistic-looking computer generated images to date, radiosity methods have not yet met with widespread acceptance. The main obstacle has been their need for very careful and time consuming user intervention, without which, current techniques are prone to generating a wide range of annoying visual artifacts. These artifacts are generally due to poor surface meshing, resulting in insufficient sampling density and ineffective sample placement. This thesis investigates the roots of this problem by taking a step back from the traditional finite element formulation of radiosity and examining the more general integral equation formulation. An analysis of the radiance functions described by this equation shows how umbra and penumbra boundaries as well as other sharp changes in illumination actually correspond to discontinuities in the radiance function and its derivatives. The results of this analysis have led to the concept of discontinuity meshing, whereby accurate approximations to the radiance functions are computed by explicitly representing their discontinuities as boundaries in the mesh. This concept has been applied to the design of a discontinuity meshing algorithm for polyhedral environments. The algorithm is embedded in a progressive refinement radiosity system and uses piecewise quadratic interpolation to reconstruct a smooth radiance function while preserving discontinuities where appropriate. The radiosity solutions produced by the new algorithm are compared against a photograph of a physical environment, an analytical solution, and a conventional, yet state-of-the-art, radiosity system, and its performance on architectural models of medium complexity is measured. The results are remarkably accurate both numerically and visually. The new discontinuity meshing algorithm drastically reduces, and in many cases eliminates, many of the annoying artifacts typical of conventional radiosity meshes, producing images of previously unattained quality. Moreover, the meshing is completely automatic and produces solutions that are highly view-independent.

title: Sorting Helps for Voronoi Diagrams
abstract: It is well known that, using standard models of computation, it requires $\Omega(n$ log n) time to build a Voronoi diagram for n data points. This follows from the fact that a Voronoi diagram algorithm can be used to sort. But if the data points are sorted before we start, can the Voronoi diagram be built any faster? We show that for certain interesting, although nonstandard types of Voronoi diagrams, sorting helps. These nonstandard types Voronoi diagrams use a convex distance function instead of the standard Euclidean distance. A convex distance function exists for any convex shape, but the distance functions based on polygons (especially triangles) lead to particularly efficient Voronoi diagram algorithms - fast algorithms using simple data structures. Specifically, a Voronoi diagram using a convex distance function based on a triangle can be built in $O(n$ log log n) time after initially sorting the n data points twice. Convex distance functions based on other polygons require more initial sorting.

title: Near-Quadratic Bounds for the L_{1} Voronoi Diagram of Moving Points
abstract: Given a set of n moving points in the plane, how many topological changes occur in the Voronoi

diagram of the points? If each point has constant velocity then there is an upper bound of $O(n^{3})$ [Guibas, Mitchell and Roos] and an easy lower bound of $\Omega(n^{2})$. It is widely believed that the true upper bound should be close to $O(n^{2})$. We show this belief to be true for the case of Voronoi diagrams based on the L_{1} (or L_{∞}) metric; the number of changes is shown to be $O(n^{2} \alpha (n))$ where $\alpha(n)$ grows so slowly it is effectively a small constant for all reasonable values of n.

title: A Lower Bound for Two-Server Balancing Algorithms
abstract: We consider the class of balancing algorithms for two servers. Such algorithms have appeared in a number of the early papers on this problem; they are so named because they seek to "balance" the distance travelled evenly among the servers. In this paper, we show a universal lower bound on the competitive ratio of any balancing algorithm for two servers. The lower bound is equal to (5 + $\sqrt{7}$)/2 ($\sim$ 3.82), and consequently shows that no optimal on-line algorithm for two servers can be expressed as a balancing algorithm.

title: Resource Bounds and Combinations of Consensus Objects
abstract: The shared-memory model of computation typically provides processes with an arbitrary number of copies of the available object types; yet a simple argument shows that any consensus protocol can only make use of some finite subset of these. Thus we believe it is useful to consider the problem of consensus from the point of view of resource bounds, determining whether consensus can still be solved when the number of copies of the system's shared objects is limited. This approach leads to a general technique which we call the combination protocol, in which the number of processes that can achieve consensus with a given object increases as more copies of it are made available. Such a phenomenon brings up questions about the robustness of Herlihy's consensus hierarchy, in that objects are being combined to solve n-process consensus, even though no single copy can do so individually. We show how the ideas in the combination protocol appear even in situations where objects are not explicitly being combined with one another; we also consider the general question of resource bounds in several known consensus protocols. We analyze two such protocols that use seemingly similar primitives, achieving a substantial improvement in one case and showing a tight lower bound in the other.

title: The Primary-Backup Approach: Lower and Upper Bounds
abstract: The most widely used approach to building replicated, fault-tolerant services is the primary-backup approach. In this approach, the state of the service is replicated across multiple servers, with one server designated as the primary and the rest as backups. Clients send requests only to the primary. However, in case the primary fails, one of the backups takes over as the new primary. Ever since it was introduced in 1976 by Alsberg and Day, the primary-backup approach has become the basis for building many practical fault-tolerant services. However, despite the widespread use, the approach has not been studied systematically, and little is known of the fundamental costs and tradeoffs of using the approach under various kinds of failures. Thus, there is a gap between theory and practice. In order to close this gap, this thesis analyzes the primary-backup approach, both from the theoretical perspective of specification, lower bounds and upper bounds, as well as from the practical viewpoint of performance tradeoffs in protocols. We identify three key cost metrics of primary-backup protocols--degree of replication, blocking time and failover time--and then show lower and upper bounds on these metrics for a hierarchy of failure models. We then implement an important subclass of our primary-backup protocols, called 0-blocking protocols, and give performance figures. In addition to leading to the development of new, more efficient protocols, we believe that the work in this thesis has resulted in a better understanding of the properties of existing primary-backup protocols.

title: A Security Architecture for Fault-Tolerant Systems
abstract: Process groups are a common abstraction for fault-tolerant computing in distributed systems. We present a security architecture that extends the process group into a security abstraction. Integral parts of this architecture are services that securely and fault-tolerantly support cryptographic key distribution using novel techniques. We detail the design and implementation of these services and the secure process group abstraction they support. We also give performance figures for some common group operations.

title: Understanding Partitions and the “No Partition” Assumption
abstract: The paper discusses partitions in asynchronous message-passing systems. In such systems slow processes and slow links can lead to virtual partitions that are indistinguishable from real ones. This raises

the following question: what is a "partition" in an asynchronous system? To overcome the impossibility of detecting crashed processes in an asynchronous system, our system model incorporates a failure suspector to detect (possibly erroneously) process failures. Based on failure suspicions we give a definition of partitions that acccounts for real partitions as well as virtual ones. We show that under certain assumptions about the process behavior, any incorrect failure suspicion inevitably partitions the system. We then show how to interpret the "absence of partition" assumption.

title: Locality in Distributed Computing
abstract: The topic of this thesis is the issue of locality in distributed computing. A first set of results in this thesis concerns the Δ-vertex coloring problem. They are all based on the following result. Let G be a graph such that $\Delta \geq 3, G$ is not a complete graph, and such that all of G except one vertex v is Δ-colored. Then, it is possible to extend this Δ-coloring to all of G by recoloring a path originating from v of length at most $O(\log_{\Delta}n)$. This property allows us to develop several efficient algorithms for Δ-coloring. In particular, but not exclusively, in the distributed and PRAM models of computation. It also implies a well-known result of Brooks as a corollary. Another set of results concerns network decomposition - a basic notion in distributed graph algorithms. We improve the bounds for computing a network decomposition distributively and deterministically. Our algorithm computes an $(n^{\epsilon(n)},n^{\epsilon(n)})$-decomposition in $O(n^{\epsilon(n)})$ time, where $\epsilon(n) = O(1/\sqrt{\log n})$. We also show that the class of graphs $\cal G$ whose maximum degree is $O(n^{\delta(n)}$, where $\delta(n) = O(1/\log \log n)$, is complete for the task of computing a ($\log n, \log n)$-decomposition, in polylogarithmic in n time. Completeness is to be intended in the following sense: if we have an algorithm $\cal A$ that computes a $(\log n, \log n)$-decomposition in polylogarithmic in n time for graphs in $\cal G$, then we can compute a $(\log n, \log n)$-decomposition in polylogarithmic in n time for all graphs. A last set of results concerns the edge coloring problem. We give a randomized distributed algorithm to compute an edge coloring of a given network G, that uses at most $1.6\Delta + \log^{2+\delta} n$ colors, for any $\delta greater than 0$. The running time is $O(\log n)$ and the failure probability is at most ϵ, for any fixed $\epsilon greater than 0$. The algorithm is quite simple but requires an interesting probabilistic analysis. At the core of the analysis is an extension of the Chernoff-Hoeffding bounds, which are fundamental tools used in estimating the tail probabilities of the sum of Bernoulli-like trials.

title: Randomized Distributed Edge Coloring via an Extension of the Chernoff-Hoeffding Bounds
abstract: Certain types of routing, scheduling and resource allocation problems in a distributed setting can be modeled as edge coloring problems. We present fast and simple randomized algorithms for edge coloring a graph, in the synchronous distributed point-to-point model of computation. Our algorithms compute an edge-coloring of a graph G with n nodes and maximum degree Δ with at most $(1.6 + \epsilon)\Delta + \log^{2+\delta} n$ colors with high probability (arbitrarily close to 1), for any fixed $\epsilon,\delta greater than 0$. To analyze the performance of our algorithms, we introduce an extension of the Chernoff-Hoeffding bounds, which are fundamental tools that are used very frequently in estimating tail probabilities. However, they assume stochastic independence among certain random variables, which may not always hold. Our results extend the Chernoff-Hoeffding bounds to certain types of random variables which are

not stochastically independent. We believe that these results are of independent interest, and merit further study.

title: On the Complexity of Distributed Network Decomposition
abstract: In this paper, we improve the bounds for computing a network decomposition, which is a basic notion in distributed graph algorithms, distributively and deterministically. Our algorithm computes an $(n^{\epsilon(n)},(n^{\epsilon(n)})$-decomposition in $O(n^{\epsilon(n)})$ time, where $\epsilon(n)=O(1/ \sqrt{\log n})$. As a corollary we obtain improved deterministic bounds for distributively computing several graph structures such as maximal independent sets and Δ-vertex colorings. We also show that the class of graphs $\cal G$ whose maximum degree is $O(n^{\delta(n)})$, where $\delta(n)=O(1/\log \log n)$, is complete for the task of computing a near-optimal decomposition, i.e., a $(\log n \log n)$-decomposition, in $O($polylog$(n))$ time. This is a corollary of a more general characterization, which pinpoints the weak points of existing network decomposition algorithms. Completeness is to be intended in the following sense: if we have an algorithm $\cal A$ that computes an optimal decomposition in $O($polylog$(n))$ time for graphs in $\cal G$, then we can compute an optimal decomposition in $O($polylog $(n))$ time for all graphs.

title: Randomness-Optimal Unique Element Isolation, With Applications to Perfect Matching and Related Problems
abstract: In this paper, we precisely characterize the randomness complexity of the unique element isolation problem, a crucial step in the RNC algorithm for perfect matching due to Mulmuley, Vazirani and Vazirani[21] and in several other applications. Given a set S and an unknown family $\cal F \subseteq$ 2^{S} with $|\cal F| \leq$ Z, we present a scheme to assign polynomially bounded weights to the elements of S, using only $O(\log Z + \log |S|)$ ransom bits, such that the minimum weight set in $\cal F$ is unique with high probability. This generalizes and improves the results of Mulmuley, Vazirani and Vazirani who give a scheme which uses $O(S \log S)$ random bits independent of Z. We also prove a matching lower bound for the randomness complexity of this problem. This new weight assignment scheme yields a randomness-efficient RNC^{2} algorithm for perfect matching which uses $O(\log Z + \log n)$ random bits where Z is any given upper bound on the number of perfect matchings in the input graph. This generalizes the result of Grigoriev and Karpinski[11] who present an NC^{3} algorithm when Z is polynomially bounded and also gives an improvement on the running time in this case. The worst-case randomness complexity of our algorithm is $O(n \log (m/n))$ random bits, as opposed to the previous bound of $O(m \log n)$ bits. Our technique also gives randomness-efficient solutions for several problems in which the unique element isolation tool is used, such as RNC algorithms for variants of matching and basic problems on linear matroids such as matroid intersection and matroid matching. We also obtain a randomness-efficient alternative to the random reduction from SAT to $USAT$, the language of uniquely satisfiable formulas, due to Valiant and Vazirani[32]. This reduction can be derandomized in the case of languages in $F ew P$ to yield new proofs of the results $F ew P \subseteq \oplus P$ and $F ew P \subseteq C_{=} P$.

title: Pseudozeros of Polynomials and Pseudospectra of Companion Matrices
abstract: It is well known that the zeros of a polynomial p are equal to the eigenvalues of the associated companion matrix A. In this paper, we take a geometric view of the conditioning of these two problems and of the stability of algorithms for polynomial zerofinding. The ϵ-pseudozero set $Z_{\epsilon}(p)$ is the set of zeros of all polynomials $\hat{p}$ obtained by coefficientwise perturbations of p of size $\leq \epsilon$; this is a subset of the complex plane considered earlier by Mosier, and is bounded by a certain generalized lemniscate. The ϵ-pseudospectrum $\Lambda_{\epsilon}(A)$ is another subset of C defined as the set of eigenvalues of matrices $\hat{A}=A+E$ with $||E|| \leq\epsilon$; it is bounded by a level curve of the resolvent of A. We find that if A is first balanced in the usual EISPACK sense, then $Z_{\epsilon||p||}(p)$ and $\Lambda_{\epsilon||A||}(A)$ are usually quite close to one another. It follows that the Matlab ROOTS algorithm of balancing the companion matrix, then computing its eigenvalues, is a stable algorithm for polynomial zerofinding. Experimental comparisons with the Jenkins-Traub (IMSL) and Madsen-Reid (Harwell) Fortran codes confirm that these three algorithms have roughly similar stability properties. Key words: polynomial zeros, comapnion matrix, pseudospectrum.

title: Alex - A Paradigm for Expressing and Compiling Matrix Functions
abstract: This work presents formal and practical tools to support the Alex paradigm for expressing and compiling matrix functions. Alex programs are recursive definitions over matrices with the same flavor as the elegant FP languages of Backus. Many useful matrix algorithms can be expressed in both FP and Alex without any explicit index arithmetic. While FP is very difficult to compile to fast numerical codes, we show that Alex functions admit compile-time analyses and code generation techniques with efficient results. In particular, we give a type system that expresses matrix sizes and shapes, a sound and complete inference algorithm for these types, and a code generation algorithm that is space-efficient--storage is allocated only for user function parameters and results. Finally, we give an algorithm that determines when it is safe to replace call by value array parameters in the compiled code with call by reference. A compiler using these techniques generates C code from Alex programs which is at least as fast as code one would write by hand for some small problems. We conclude with discussion of how the fundamental techniques given here relate to previous work and how they should be extended to a general functional language or incorporated as a feature of an existing one.

title: Decidability of Systems of Set Constraints with Negative Constraints
abstract: Set constraints are relations between sets of terms. They have been used extensively in various applications in program analysis and type inference. Recently, several algorithms for solving general systems of positive set constraints have appeared. In this paper, we consider systems of mixed positive and negative constraints, which are considerably more expressive than positive constraints alone. We show that it is decidable whether a given such system has a solution. The proof involves a reduction to a number-theoretic decision problem that may be of independent interest.

title: Principled Optimization of Functional Programs
abstract: Automatic optimizers for computer programs work with a fixed list of rote transformations, while human programmers can go on to derive new optimizations from broad and intuitive principles if known transformations prove inadequate. This dissertation investigates the possibility that principled optimization can be automated, focusing on a single principle (the principle that programs should not do anything unnecessary) and a single program domain (the domain of purely functional, first-order programs). Three questions are explored: How can the principle be formalized? How can violations of the principle be detected? How can violations be repaired? The trace grammar is a new representation for first-order functional programs. It permits a simple formal statement of the optimizing principle. A trace grammar is a kind of graph grammar. An individual graph represents a path of execution through the program, without any loops or conditionals. The grammar for a program generates a language of graphs representing the possible paths of execution through that program. Trace grammars provide unique leverage for the twin problems of identifying and repairing violations of the principle. Detecting violations of the principle is a problem in semantic analysis. A new method of inference, the relational constraint method, helps make this tractable. The method treats a trace graph as a system of constraints on a lattice of binary relations, and uses those constraints to develop the strongest relation it can find for each pair of values in the graph. Repairing violations is not easy: given an example of an unnecessary computation performed by the program, one wants to modify the program so that it never makes that mistake. This grammar thinning problem for trace grammars corresponds to an interesting open problem on context-free grammars. An (approximate) solution to this CFG problem yields an optimization technique for trace grammars. An optimizer called Thinner is the proof-of-concept for these ideas. Using the techniques outlined above, Thinner rediscovers a variety of common compiler optimizations. It also finds other, more exotic transformations, including the well-known Fibonacci reformulation. Thinner demonstrates the potential of the principled approach as a high-powered optimizing tool.

title: Stable Finite Elements for Problems With Wild Coefficients
abstract: We consider solving an elliptic boundary value problem in the case that the coefficients vary by many orders of magnitude over the domain. A linear finite element method is used. It is shown that the standard method for solving the resulting linear equations in finite-precision arithmetic can give an arbitrarily inaccurate answer because of ill-conditioning in the stiffness matrix. A new method for solving the linear equations is proposed. This method is based on a "mixed formulation" and gives a numerically accurate answer independent of the variation in the coefficients. The numerical error in the solution of the linear system for the new method is shown to depend on the aspect ratio of the triangulation.

title: Finding Regions Fast: Single Entry Single Exit and Control Regions in Linear Time
abstract: Many compilation problems require computing the control dependence equivalence relation which

divides nodes in a control flow graph into equivalence classes such that nodes are in the same class if and only if they have the same set of control dependences. In this paper, we show that this relation can be computed in $O(E)$ time by reducing it to a naturally stated graph problem: in a strongly connected component, divide nodes into equivalence classes such that every cycle passes through all or none of the nodes in an equivalence class. Our algorithm does not require the computation of the control dependence relation or of the postdominator relation - in fact, it runs faster in practice than the best algorithms for either of these problems. We also show that our algorithm can be used to determine the single entry single exit regions of a control flow graph in $O(E)$ time.

title: Selective Text Utilization and Text Traversal
abstract: Many large collections of full-text documents are currently stored in machine-readable form and processed automatically in various ways. These collections may include different types of documents, such as messages, research articles, and books, and the subject matter may vary widely. To process such collections, robust text analysis methods must be used, capable of handling materials in arbitrary subject areas, and flexible access must be provided to texts and text excerpts of varying size. In this study, global text comparison methods are used to identify similarities between text elements, followed by local context-checking operations that resolve ambiguities and distinguish superficially similar texts from texts that actually cover identical topics. A linked text structure is then created that relates similar texts at various levels of detail. In particular, text links are available for full texts, as well as text sections, paragraphs, and sentence groups. The linked structures are usable to identify important text packages, to traverse texts selectively both within particular documents and between documents, and to provide flexible text access to large text collections in response to various kinds of user needs. An automated 29-volume encyclopedia is used as an example to illustrate the text accessing and traversal operations.

title: Chernoff-Hoeffding Bounds for Applications with Limited Independence
abstract: Chernoff-Hoeffding bounds are fundamental tools used in bounding the tail probabilities of the sums of bounded and independent random variables. We present a simple technique which gives slightly better bounds than these and which, more importantly, requires only limited independence among the random variables, thereby importing a variety of standard results to the case of limited independence for free. Additional methods are also presented, and the aggregate results are very sharp and provide a better understanding of the proof techniques behind these bounds. They also yield improved bounds for various tail probability distributions and enable improved approximation algorithms for jobshop scheduling. The "limited independence" result implies that weaker sources of randomness are sufficient for randomized algorithms whose analyses use the Chernoff-Hoeffding bounds; further, it leads to algorithms that require a reduced amount of randomness for any analysis which uses the Chernoff-Hoeffding bounds, e.g., the analysis of randomized algorithms for random sampling and oblivious packet routing.

title: The Group Membership Problem in Asynchronous Systems
abstract: The thesis formally defines the class of Process Group Membership Problems (GMP) for asynchronous systems. These problems involve maintaining a list of processes belonging to the system, and updating it as processes join (are started) and leave (terminate or fail). We investigate closely the strongest member of the GMP class. Strong GMP presents this list in a consistent manner to all processes using it: the sequence of joins and leaves are identical. We show that despite prevalent beliefs, strong consistency and efficiency are not conflicting goals. This should have significant implications for distributed systems since the need for process membership agreement arises in many canonical problems in distributed computing. We present an inexpensive means (the S-GMP algorithm) of assuring complete, system-wide agreement on process membership. We discuss the role of process membership in distributed systems and how to use S-GMP to build a Membership Resource Manager (MRM). The thesis also examines whether any weaker member of the GMP class suffices to specify an MRM. In doing so we justify using Strong GMP over two much weaker GMP instances in three important ways. First, by comparing Strong GMP and its minimal solution with the weaker instances and their minimal solutions, we arrive at the surprising result that Strong GMP is often less expensive than the others, notably in executions in which membership changes are frequent. Second, we show that a membership service defined by Strong GMP is more robust, more responsive and more adaptable than a membership service defined by weaker GMP instances. Third, we compare membership services defined by the various GMPs according to the utility each service provides higher-level, distributed applications. That is, ignoring implementation costs, how useful are the different GMP consistency guarantees as a platform on which to build distributed solutions to distributed problems? We show that the consistency guarantees of Strong GMP make it (i.e. and the membership service Strong GMP defines) more useful to higher-level distributed applications. Finally, the thesis presents experimental results from implementing S-GMP. The data demonstrate that a centralized Membership Resource Manager is a non-intrusive service around which to design distributed systems and provide system-wide consistency. The data quantify and help clarify the tradeoffs between replication degree, overall system size and process failure frequency. These initial results should guide future MRM design and development.

title: Simplical Mesh Generation With Applications
abstract: Many problems in computer graphics and in engineering analysis require for their solution the construction of a mesh of simple polytopal elements that approximately fill the interior of an object or cover its boundary. The simplest polytopes are the simplexes, and simplicial meshes have particular advantages when solving interpolation problems, graphically rendering objects approximated by boundary meshes, and in many other applications. Boxes are often used where simplexes should be considered because the properties of boxes are more familiar. This dissertation develops several techniques that aid in the construction of simplicial meshes in any dimension. It presents the essential combinatorial and geometric properties of simplexes, and presents simple techniques for decomposing simplexes into smaller simple objects. It

describes the simplicial quadtree, a useful representation in the construction of simplicial meshes, and presents a technique for converting an arbitrary simplicial quadtree into a balanced quadtree, then into a triangulation. It also describes mesh displacement, a technique for improving the quality of a boundary triangulation while reducing its size. Several degenerate behaviors can arise from mesh displacement, and the dissertation discusses methods for detecting and compensating for these degeneracies. Simplicial mesh generation techniques can be applied to many kinds of problems. To illustrate this, the final chapters describe the implementation of a polygonalizer for algebraic sets and a system that applies the operations of constructive solid geometry to sets defined algebraically.

title: A Security Architecture for Fault-Tolerant Systems
abstract: While there is considerable experience with addressing the needs for security and fault-tolerance individually in distributed systems, much less is understood about how to simultaneously address these needs in a single, integrated solution. Indeed, the goals of security and availability have traditionally been viewed as being in conflict, because replicationg data and services for availability makes them inherently harder to protect. This thesis presents the design and implementation of a security architecture for fault-tolerant systems, including a set of results that underpin this architecture. We first present a methodology for balancing the aforementioned tradeoff between security and availability in distributed services. Using our techniques, a service can be replicated so that it will remain available and correct despite the corruption of some servers and clients by a malicious intruder. These results include the identification and prevention of a new form of attack in which an intruder effects and exploits violations of causality in the sequence of requests processed by the service. Second, we bring this replication methodology and other novel techniques to bear on an issue for which the conflict between security and availability is particularly troublesome, namely cryptographic key distribution via trusted services. We present authentication and time services that can securely and fault-tolerantly support cryptographic key distribution in a wide range of settings. Third, we present the design and implementation of our security architecture, which employs these services. The architecture supports process groups --a common paradigm of fault-tolerant computing--as its primary security abstraction, and provides tools to construct applications that are resilient to benign failures and malicious attacks. We discuss the integration of this architecture in the Horus system and focus on techniques to make group communication secure and efficient. In the final contributions of the thesis, we further explore the importance of detecting causal relationships for security. We present a framework for examining attacks onaattempts to detect causal relationships. We also present several algorithms to prevent these attacks in some situations.

title: Verification of Temporal Properties
abstract: The paper presents a relatively complete deductive system for proving branching time temporal properties of reactive programs. No deductive system for verifying branching time temporal properties has been presented before. Our deductive system enjoys the following advantages. First, given a well-formed specification there is no need to translate it into a normal-form specification since the system can handle any well-formed specification. Second, given a specification to be verified, the proof rule to be applied is easily determined according to the top level operator of the specification. Third, the system reduces temporal

verification to assertional reasoning rather than to temporal reasoning.
